

**SUBVENTE<sup>®</sup> lamotrigine tablet**  
**SUBVENTE<sup>®</sup> lamotrigine**  
**OWP Pharmaceuticals, Inc.**

**HIGHLIGHTS OF PRESCRIBING INFORMATION**

These highlights do not include all the information needed to use SUBVENTE safely and effectively. See full prescribing information for SUBVENTE.

**SUBVENTE (lamotrigine) tablets, for oral use**

Initial U.S. Approval: 1994

**WARNING: SERIOUS SKIN RASHES**  
See full prescribing information for complete boxed warning.  
Cases of life-threatening serious rashes, including Stevens-Johnson syndrome and toxic epidermal necrolysis, and/or rash-related death have been reported for lamotrigine. The risk of serious rash is greater in pediatric patients than in adults. Additional factors that may increase the risk of rash include:  
• concomitant use with valproate  
• exceeding recommended initial dose of SUBVENTE,  
• exceeding recommended dose escalation for SUBVENTE.  
• presence of the HLA-B\*57:02 allele. (5.3)  
Serious rashes are also caused by lamotrigine; however, it is not possible to predict which rashes will prove to be serious or life-threatening. SUBVENTE should be discontinued at the first sign of rash, unless the rash is clearly not drug related. (5.1)

**RECENT MAJOR CHANGES**

Boxed Warning 10/2025  
Dosage and Administration (2.1, 2.2, 2.4) 10/2025  
Warnings and Precautions 10/2025  
Serious Skin Rashes 10/2025  
Concomitant Use with Estrogen-Containing Products, Including Oral Contraceptives (5.9) 4/2025  
Sudden Unexplained Death in Children (5.12) 4/2025

**INDICATIONS AND USAGE**

SUBVENTE is indicated for:  
**Adjunctive Therapy**—for the treatment of partial-onset seizures and primary generalized tonic-clonic (PGTC) seizures.  
**Monotherapy**—for the treatment of Lennox-Gastaut syndrome. (1.1)

**Subvente monotherapy is an off-label use. It should not be used in combination with monotherapy in patients with partial-onset seizures who are the major or primary seizure type, including patients who are treated with carbamazepine, phenytoin, phenobarbital, or valproate.** (1.1)  
**Subvente** Maintenance treatment of bipolar I disorder to delay the time to occurrence of mood episodes in patients treated for acute mood episodes with standard therapy. (2)  
**Limitations of Use** Treatment of acute mania or mixed episodes is not recommended. Effectiveness of SUBVENTE in the acute treatment of mood episodes has not been established.

**DOSEAGE AND ADMINISTRATION**

**Initial Dosing**—See Table 1 for patients older than 12 years and Tables 2 and 3 for patients aged 2 to 12 years. (2.1)  
Conversion to monotherapy—See Table 4. (2.3)  
Subvente should be discontinued due to rash unless the potential benefits clearly outweigh the risks. (2.1, 3.1)  
Adjustments to maintenance doses will be necessary in most patients starting or stopping estrogen-containing products, including oral contraceptives. (2.1, 5.9)  
Discontinuation: Taper over a period of at least 2 weeks (approximately 50% dose reduction per week). (2.1, 5.10)

**Warnings**

• **Adjunctive Therapy**—See Table 1 for patients older than 12 years and Tables 2 and 3 for patients aged 2 to 12 years. (2.1)  
• **Conversion to monotherapy**—See Table 4. (2.3)

**Subvente**

• **Subvente** See Tables 5 and 6. (2.4)  
• **Tablets**: 25 mg, 100 mg, 150 mg, and 200 mg, scored. (3.1, 16)

**CONTRAINDICATIONS**

Hypersensitivity to the drug or its ingredients. (Contraindication, 4)

**WARNINGS AND PRECAUTIONS**

• **Life-threatening serious rash and/or rash-related death**. Discontinue at the first sign of rash, unless the rash is clearly not drug related. (Boxed Warning, 5.1)  
• **Hemophagocytic lymphohistiocytosis**. Compare the drug pros and cons and evaluate patients immediately if they develop signs of symptoms. Discontinue SUBVENTE if an alternative therapy is not established. (5.2)  
• **Rapid or life-threatening hypersensitivity reaction**. Multisystem hypersensitivity reactions, also known as drug reaction with eosinophilia and systemic symptoms, may be fatal or life-threatening. Early signs may include rash, fever, and lymphadenopathy. These reactions may be associated with other organ involvement, such as hepatitis, hepatic failure, blood dyscrasias, or acute interstitial nephritis. SUBVENTE should be discontinued. Laboratory testing for the reaction is not found. (5.3)  
• **Cardiac rhythm and conduction abnormalities**. Based on in vitro findings, SUBVENTE could cause ventricular arrhythmias and/or death in patients with certain underlying cardiac disorders or arrhythmias. Any potential or observed benefit of SUBVENTE in an individual patient with clinically important structural or functional heart disease must be carefully weighed against the risk for serious arrhythmias and/or death for that patient. (5.4)  
• **Blood dyscrasias (e.g., neutropenia, thrombocytopenia, pancytopenia)**. May occur, either with or without an associated hypersensitivity syndrome. Monitor for signs of anemia, unexpected infection, or bleeding. (5.5)  
• **Suicidal behavior and ideation**. Monitor for signs of suicidality. (5.7)  
• **Asceptic meningitis**. Monitor for signs of meningitis. (5.8)  
• **Medication errors due to product name confusion**. Strongly advise patients to visually inspect tablets to verify the correct drug is correct. (5.8, 16, 17)

**ADVERSE REACTIONS**

**Subvente** Most common adverse reactions (incidence ≥ 5% in adults and ≥ 2% in children) were dizziness, headache, diplopia, nausea, blurred vision, somnolence, fatigue, pharyngitis, and rash. Additional adverse reactions (incidence ≥ 1% reported in children included vomiting, infection, fever, accidental injury, diarrhea, abdominal pain, and tremor. (6.1)  
**Subvente** Most common adverse reactions (incidence ≥ 5% in adults were nausea, insomnia, somnolence, dizziness, fatigue, rash, tremor, abnormal pain, and weakness. (6.1)  
**Subvente** Most common adverse reactions (incidence ≥ 1% in children were dizziness, headache, diplopia, nausea, blurred vision, somnolence, fatigue, pharyngitis, and rash. (6.1)  
To report SUSPECTED ADVERSE REACTIONS, contact OWP Pharmaceuticals, Inc. at 1-800-273-4729 or FDA at 1-800-FDA-1088 or www.fda.gov/medwatch.

**DRUG INTERACTIONS**

• Valproate increases lamotrigine concentrations more than 2-fold. (7.1, 12.3)  
• Carbamazepine, phenytoin, phenobarbital, primidone, and diazepam decrease lamotrigine concentrations by approximately 50%. (7.1, 12.3)  
• Estrogen-containing oral contraceptives decrease lamotrigine concentrations by approximately 50%. (5.9, 12.3)  
• Fosphenytoin, topiramate, and zonisamide decrease lamotrigine exposure by approximately 50% and 52%, respectively. (7.1, 12.3)  
• Coadministration with organic cationic transporter 2 substrates with narrow therapeutic index is not recommended. (7.1, 12.3)

**USE IN SPECIFIC POPULATIONS**

• **Pregnancy** based on animal data may cause fetal harm. (8.1)  
• **Hepatic impairment**: Dose adjustments required in patients with moderate and severe liver impairment. (2.1, 8.6)  
• **Renal impairment**: Reduced maintenance doses may be effective for patients with significant renal impairment. (2.1, 8.7)

**See 17 for PATIENT COUNSELING INFORMATION and Medication Guide.**

\* Some of the subsections contained from the full prescribing information are not listed.

**FULL PRESCRIBING INFORMATION**

**WARNING: SERIOUS SKIN RASHES**  
SUBVENTE can cause serious rashes requiring hospitalization and discontinuation of treatment. The incidence of these rashes, which have included Stevens-Johnson syndrome, is approximately 0.3% to 0.8% in pediatric patients (aged 2 to 17 years) and 0.08% to 0.3% in adults receiving SUBVENTE. One rash-related death was reported in a prospectively followed cohort of 1,983 pediatric patients (aged 2 to 16 years) with epilepsy taking SUBVENTE as adjunctive therapy. In worldwide postmarketing experience, rare cases of toxic epidermal necrolysis and/or rash-related death have been reported in adult and pediatric patients, but their numbers are too few to permit a precise estimate of the rate.  
In addition to app, factors that may increase the risk of occurrence or the severity of rash caused by SUBVENTE include: (1) concomitant use of SUBVENTE with valproate (includes valproic acid and divalproex sodium), (2) exceeding the recommended initial dose of SUBVENTE, (3) exceeding the recommended dose escalation for SUBVENTE, or (4) the presence of the HLA-B\*57:02 allele. However, cases have occurred in the absence of these factors.  
Nearly all cases of life-threatening rashes caused by SUBVENTE have occurred within 2 to 6 weeks of treatment initiation. However, isolated cases have occurred after prolonged treatment (e.g., 6 months). Accordingly, duration of therapy cannot be relied upon as means to predict the potential risk heralded by the first appearance of a rash.  
Although benign rashes are also caused by SUBVENTE, it is not possible to predict reliably which rashes will prove to be serious or life-threatening. Accordingly, SUBVENTE should ordinarily be discontinued at the first sign of rash, unless the rash is clearly not drug related. Discontinuation of treatment may not prevent a rash from becoming life threatening or permanently disabling or disfiguring (See Warnings and Precautions (5.1)).

**1 INDICATIONS AND USAGE**

**1.1 Epilepsy**

**Adjunctive Therapy**

SUBVENTE is indicated as adjunctive therapy for the following seizure types in patients aged 2 years and older:

- partial-onset seizures.
- primary generalized tonic-clonic (PGTC) seizures.
- generalized seizures of Lennox-Gastaut syndrome.

**Monotherapy**

SUBVENTE is indicated for conversion to monotherapy in adults (aged 16 years and older) with partial-onset seizures who are receiving treatment with carbamazepine, phenytoin, phenobarbital, primidone, or valproate as the single antiepileptic drug (AED).

Safety and effectiveness of SUBVENITE have not been established (1) as initial monotherapy, (2) for conversion to monotherapy from AEDs other than carbamazepine, phenytoin, phenobarbital, primidone, or valproate, or (3) for anticonvulsant conversion to monotherapy from 2 or more concomitant AEDs.

**1.2 Bipolar Disorder**

SUBVENITE is indicated for the maintenance treatment of bipolar I disorder to delay the time to occurrence of mood episodes (depression, mania, hypomania, mixed episodes) in patients treated for acute mood episodes with standard therapy [see Clinical Studies (14.7)].

**Limitations of Use**

Treatment of acute manic or mixed episodes is not recommended. Effectiveness of SUBVENITE in the acute treatment of mood episodes has not been established.

**2 DOSAGE AND ADMINISTRATION**

**2.1 General Dosing Considerations**

**Rash**  
There are suggestions that the risk of severe, potentially life-threatening rash may be increased by (1) coadministration of SUBVENITE with valproate, (2) exceeding the recommended initial dose of SUBVENITE, or (3) exceeding the recommended dose escalation for SUBVENITE. However, cases have occurred in the absence of these factors [see Boxed Warning]. Therefore, it is important that the dosing recommendations be followed closely.

The risk of nonserious rash may be increased when the recommended initial dose and/or the rate of dose escalation for SUBVENITE is exceeded and in patients with a history of allergy or rash to other AEDs.

SUBVENITE Starter Kits provide SUBVENITE at doses consistent with the recommended titration schedule for the first 3 weeks of treatment, based upon concomitant medications, for patients with epilepsy (older than 12 years) and bipolar I disorder (adults) and are intended to help reduce the potential for rash. The use of SUBVENITE Starter Kits is recommended for appropriate patients who are starting or restarting SUBVENITE [see How Supplied/Storage and Handling (14.1)].

It is recommended that SUBVENITE not be restarted in patients who discontinued due to rash associated with prior treatment with lamotrigine unless the potential benefits clearly outweigh the risks. If the decision is made to restart a patient who has discontinued SUBVENITE, the need to restart with the initial dosing recommendations should be assessed. The greater the interval of time since the previous dose, the greater consideration should be given to restarting with the initial dosing recommendations. If a patient has discontinued lamotrigine for a period of more than 3 half-lives, it is recommended that initial dosing recommendations and guidelines be followed. The half-life of lamotrigine is affected by other concomitant medications [see Clinical Pharmacology (12.3)].

**SUBVENITE Added to Drugs Known to Induce or Inhibit Glucuronidation**

Because lamotrigine is metabolized predominantly by glucuronic acid conjugation, drugs that are known to induce or inhibit glucuronidation may affect the apparent clearance of lamotrigine. Drugs that induce glucuronidation include carbamazepine, phenytoin, phenobarbital, primidone, rifampin, estrogen-containing products, including oral contraceptives, and the protease inhibitors lopinavir/ritonavir and atazanavir/ritonavir. Lamotrigine inhibits glucuronidation. For dosing considerations for SUBVENITE in patients on estrogen-containing products, including contraceptives, and atazanavir/ritonavir, see below and Table 13. For dosing considerations for SUBVENITE in patients on other drugs known to induce or inhibit glucuronidation, see Tables 1, 2, 5, 6, and 13.

**Target Plasma Levels for Patients with Epilepsy or Bipolar Disorder**

A therapeutic plasma concentration range has not been established for lamotrigine. Dosing of SUBVENITE should be based on therapeutic response [see Clinical Pharmacology (12.3)].

**Women Taking Estrogen-Containing Oral Contraceptives**

Starting SUBVENITE in Women Taking Estrogen-Containing Oral Contraceptives: Although estrogen-containing oral contraceptives have been shown to increase the clearance of lamotrigine, no adjustments to the recommended dose escalation guidelines for SUBVENITE should be necessary solely based on the use of estrogen-containing oral contraceptives [see Clinical Pharmacology (12.3)]. Therefore, dose escalation should follow the recommended guidelines for initiating adjunctive therapy with SUBVENITE based on the concomitant AED or other concomitant medications [see Tables 1, 5, and 7]. See below for adjustments to maintenance doses of SUBVENITE in women taking estrogen-containing oral contraceptives.

**Adjustments to the Maintenance Dose of SUBVENITE in Women Taking Estrogen-Containing Oral Contraceptives**

(1) **Taking Estrogen-Containing Oral Contraceptives in women not taking carbamazepine, phenytoin, phenobarbital, primidone, or other drugs such as rifampin and the protease inhibitors lopinavir/ritonavir and atazanavir/ritonavir that induce lamotrigine glucuronidation:** the maintenance dose of SUBVENITE will in most cases need to be increased by as much as 2-fold over the recommended target maintenance dose to maintain a consistent lamotrigine plasma level [see Drug Interactions (7), Clinical Pharmacology (12.3)].

(2) **Starting Estrogen-Containing Oral Contraceptives:** In women taking a stable dose of SUBVENITE and not taking carbamazepine, phenytoin, phenobarbital, primidone, or other drugs such as rifampin and the protease inhibitors lopinavir/ritonavir and atazanavir/ritonavir that induce lamotrigine glucuronidation, the maintenance dose will in most cases need to be increased by as much as 2-fold to maintain a consistent lamotrigine plasma level [see Drug Interactions (7), Clinical Pharmacology (12.3)]. The dose increases should begin at the same time that the oral contraceptive is introduced and continue, based on clinical response, no more rapidly than 50 to 100 mg/day every week. Dose increases should not exceed the recommended rate [see Tables 1 and 5] unless lamotrigine plasma levels or clinical response support larger increases. Gradual transient increases in lamotrigine plasma levels may occur during the week of inactive hormonal preparation (pill-free week), and these increases will be greater if dose increases are made in the days before or during the week of inactive hormonal preparation. Increased lamotrigine plasma levels could result in additional adverse reactions, such as dizziness, ataxia, and diplopia. If adverse reactions attributable to SUBVENITE consistently occur during the pill-free week, dose adjustments to the overall maintenance dose may be necessary. Dose adjustments limited to the pill-free week are not recommended. For women taking SUBVENITE in addition to carbamazepine, phenytoin, phenobarbital, primidone, or other drugs such as rifampin and the protease inhibitors lopinavir/ritonavir and atazanavir/ritonavir that induce lamotrigine glucuronidation, no adjustment to the dose of SUBVENITE should be necessary [see Drug Interactions (7), Clinical Pharmacology (12.3)].

(3) **Stopping Estrogen-Containing Oral Contraceptives:** In women not taking carbamazepine, phenytoin, phenobarbital, primidone, or other drugs such as rifampin and the protease inhibitors lopinavir/ritonavir and atazanavir/ritonavir that induce lamotrigine glucuronidation, the maintenance dose of SUBVENITE will in most cases need to be decreased by as much as 50% in order to maintain a consistent lamotrigine plasma level [see Drug Interactions (7), Clinical Pharmacology (12.3)]. The decrease in dose of SUBVENITE should not exceed 25% of the total daily dose per week over a 2-week period, unless clinical response or lamotrigine plasma levels indicate otherwise [see Clinical Pharmacology (12.3)]. In women taking SUBVENITE in addition to carbamazepine, phenytoin, phenobarbital, primidone, or other drugs such as rifampin and the protease inhibitors lopinavir/ritonavir and atazanavir/ritonavir that induce lamotrigine glucuronidation, no adjustment to the dose of SUBVENITE should be necessary [see Drug Interactions (7), Clinical Pharmacology (12.3)].

**Women and Other Hormonal Contraceptive Preparations or Hormone Replacement Therapy**

The effect of other hormonal contraceptive preparations or hormone replacement therapy (HRT) on the pharmacokinetics of lamotrigine has not been systematically evaluated. Other estrogen-containing therapies, such as HRT, may interfere with lamotrigine. Therefore, close clinical monitoring on effectiveness of SUBVENITE with dose adjustment may be necessary [see Warnings and Precautions (5.3)]. It has been reported that ethinyl estradiol, not progestogens, increased the clearance of lamotrigine up to 2-fold, and the progestin-only pill had no effect on lamotrigine plasma levels. Therefore, adjustments to the dosage of SUBVENITE in the presence of progestogens alone will likely not be needed.

**Patients Taking Atazanavir/Ritonavir**

While atazanavir/ritonavir does reduce the lamotrigine plasma concentration, no adjustments to the recommended dose-escalation guidelines for SUBVENITE should be necessary solely based on the use of atazanavir/ritonavir. Dose escalation should follow the recommended guidelines for initiating adjunctive therapy with SUBVENITE based on concomitant AED or other concomitant medications [see Tables 1, 2, and 7]. In patients already taking maintenance doses of SUBVENITE and not taking glucuronidation inducers, the dose of SUBVENITE may need to be increased if atazanavir/ritonavir is added or decreased if atazanavir/ritonavir is discontinued [see Clinical Pharmacology (12.3)].

**Patients with Hepatic Impairment**

Experience in patients with hepatic impairment is limited. Based on a clinical pharmacology study in 24 subjects with mild, moderate, and severe liver impairment, the following general recommendations can be made [see Use in Specific Populations (6)]. Clinical Pharmacology (12.3). No dosage adjustment is needed in patients with mild liver impairment. Initial, escalation, and maintenance doses should generally be reduced by approximately 25% in patients with moderate and severe liver impairment without ascites and 50% in patients with severe liver impairment with ascites. Escalation and maintenance doses may be adjusted according to clinical response.

**Patients with Renal Impairment**

Initial doses of SUBVENITE should be based on patients' concomitant medications (see Tables 1 to 3 and 5); reduced maintenance doses may be effective for patients with significant renal impairment [see Use in Specific Populations (6.7), Clinical Pharmacology (12.3)]. Few patients with severe renal impairment have been evaluated during chronic treatment with SUBVENITE. Because there is inadequate experience in this population, SUBVENITE should be used with caution in these patients.

**Discontinuation Strategy**

Epilepsy: For patients receiving SUBVENITE in combination with other AEDs, a re-evaluation of all AEDs in the regimen should be considered if a change in seizure control or an appearance or worsening of adverse reactions is observed.

If a decision is made to discontinue therapy with SUBVENITE, a step-wise reduction of dose over at least 2 weeks (approximately 50% per week) is recommended unless safety concerns require a more rapid withdrawal [see Warnings and Precautions (5.10)]. Discontinuing carbamazepine, phenytoin, phenobarbital, primidone, or other drugs such as rifampin and the protease inhibitors lopinavir/ritonavir and atazanavir/ritonavir that induce lamotrigine glucuronidation should prolong the half-life of lamotrigine; discontinuing valproate should shorten the half-life of lamotrigine.

Bipolar Disorder: In the controlled clinical trials, there was no increase in the incidence, type, or severity of adverse reactions following abrupt termination of SUBVENITE. In the clinical development program in adults with bipolar disorder, 2 patients experienced seizures shortly after abrupt withdrawal of SUBVENITE. Discontinuation of SUBVENITE should involve a step-wise reduction of dose over at least 2 weeks (approximately 50% per week) unless safety concerns require a more rapid withdrawal [see Warnings and Precautions (5.10)].

**2.2 Epilepsy-Adjunctive Therapy**

This section provides specific dosing recommendations for patients older than 12 years and patients aged 2 to 12 years. Within each of these age-groups, specific dosing recommendations are provided depending upon concomitant AEDs or other concomitant medications [see Table 1 for patients older than 12 years and Table 2 for patients aged 2 to 12 years]. A weight-based dosing guide for patients aged 2 to 12 years on concomitant valproate is provided in Table 3.

**Patients Older than 12 Years**

Recommended dosing guidelines are summarized in Table 1.

**Table 1. Escalation Regimen for SUBVENITE in Patients Older than 12 Years with Epilepsy**

	In Patients TAKING Valproate *	In Patients NOT TAKING Carbamazepine, Phenytoin, Phenobarbital, Primidone or Valproate *	In Patients TAKING Carbamazepine, Phenytoin, Phenobarbital, or Primidone and NOT TAKING Valproate *
Weeks 1 and 2	25 mg every other day	25 mg every day	50 mg/day
Weeks 3 and 4	25 mg every day	50 mg/day	100 mg/day (in 2 divided doses)
Week 5 onward to maintenance	50 mg/day every 1 to 2 weeks	Increase by 25 to 50 mg/day every 1 to 2 weeks	Increase by 100 mg/day every 1 to 2 weeks
Usual maintenance dose	100 to 200 mg/day with valproate alone or other drugs that induce glucuronidation; 1 or 2 divided doses	225 to 375 mg/day (in 2 divided doses)	300 to 500 mg/day (in 2 divided doses)

\* Valproate has been shown to inhibit glucuronidation and decrease the apparent clearance of lamotrigine [see Drug Interactions (7), Clinical Pharmacology (12.3)].

† Drugs that induce lamotrigine glucuronidation and increase clearance, other than the specified AEDs, include estrogen-containing oral contraceptives, rifampin, and the protease inhibitors lopinavir/ritonavir and atazanavir/ritonavir. Dosing recommendations for estrogen-containing products, including oral contraceptives, and the protease inhibitor atazanavir/ritonavir can be found in General Dosing Considerations [see Dosage and Administration (2.1)]. Patients on rifampin and the protease inhibitor lopinavir/ritonavir should follow the same dosing titration/maintenance regimen used with AEDs that induce glucuronidation and increase clearance [see Dosage and Administration (2.1), Drug Interactions (7), Clinical Pharmacology (12.3)].

**Patients Aged 2 to 12 Years**

Recommended dosing guidelines are summarized in Table 2.

Lower starting doses and slower dose escalations than those used in clinical trials are recommended because of the suggestion that the risk of rash may be decreased by lower starting doses and slower dose escalations. Therefore, maintenance doses will take longer to reach in clinical practice than in clinical trials. It may take several weeks to months to achieve an individualized maintenance dose. Maintenance doses in patients weighing <30 kg, regardless of age or concurrent AED, may need to be increased as much as 50%, based on clinical response.

**Table 2. Escalation Regimen for SUBVENTE in Patients Aged 2 to 12 Years with Epilepsy**

	In Patients TAKING Valproate <sup>a</sup> or Valproate <sup>b</sup>	In Patients NOT TAKING Carbamazepine, Phenytoin, Phenobarbital, Primidone <sup>c</sup> or Valproate <sup>a</sup>	In Patients TAKING Carbamazepine, Phenytoin, Phenobarbital, or Primidone <sup>c</sup> and NOT TAKING Valproate <sup>a</sup>
Weeks 1 and 2	0.15 mg/kg/day in 1 or 2 divided doses, rounded down to the nearest whole tablet (see Table 3 for weight-based dosing guide)	0.3 mg/kg/day in 1 or 2 divided doses, rounded down to the nearest whole tablet	0.6 mg/kg/day in 2 divided doses, rounded down to the nearest whole tablet
Weeks 3 and 4	0.3 mg/kg/day in 1 or 2 divided doses, rounded down to the nearest whole tablet (see Table 3 for weight-based dosing guide)	0.6 mg/kg/day in 2 divided doses, rounded down to the nearest whole tablet	1.2 mg/kg/day in 2 divided doses, rounded down to the nearest whole tablet
Week 5 onward to maintenance	The dose should be increased every 1 to 2 weeks as follows: calculate 0.3 mg/kg/day, round this amount down to the nearest whole tablet, and add this amount to the previously administered daily dose.	The dose should be increased every 1 to 2 weeks as follows: calculate 0.6 mg/kg/day, round this amount down to the nearest whole tablet, and add this amount to the previously administered daily dose.	The dose should be increased every 1 to 2 weeks as follows: calculate 1.2 mg/kg/day, round this amount down to the nearest whole tablet, and add this amount to the previously administered daily dose.
Usual maintenance dose	1 to 5 mg/kg/day (maximum 200 mg/day in 1 or 2 divided doses)	4.5 to 7.5 mg/kg/day (maximum 300 mg/day in 2 divided doses)	5 to 15 mg/kg/day (maximum 400 mg/day in 2 divided doses)
Maintenance dose in patients <30 kg	1 to 3 mg/kg/day with valproate alone. May need to be increased by as much as 50%, based on clinical response.	May need to be increased by as much as 50%, based on clinical response.	May need to be increased by as much as 50%, based on clinical response.

**Note: Only whole tablets should be used for dosing.**

<sup>a</sup>Valproate has been shown to inhibit glucuronidation and decrease the apparent clearance of lamotrigine (see Drug Interactions (7), Clinical Pharmacology (12.3)).

<sup>b</sup>Drugs that induce lamotrigine glucuronidation and increase clearance, other than the specified AEDs, include estrogen-containing oral contraceptives, rifampin, and the protease inhibitors lopinavir/ritonavir and atazanavir/ritonavir. Dosing recommendations for estrogen-containing products, including oral contraceptives, and the protease inhibitor atazanavir/ritonavir, can be found in General Dosing Considerations (see Dosage and Administration (2.1)). Patients on rifampin and the protease inhibitor lopinavir/ritonavir should follow the same dosing titration/maintenance regimen used with AEDs that induce glucuronidation and increase clearance (see Dosage and Administration (2.1), Drug Interactions (7), Clinical Pharmacology (12.3)).

**Table 3. The Initial Weight-Based Dosing Guide for Patients Aged 2 to 12 Years Taking Valproate (Weeks 1 to 4) with Epilepsy**

If the patient's weight is greater than and less than	Give this daily dose, using the most appropriate combination of lamotrigine 2- and 5-mg tablets	
	Weeks 1 and 2	Weeks 3 and 4
0-7 kg	2 mg every other day	2 mg every day
7-11 kg	2 mg every day	4 mg every day
11-15 kg	4 mg every day	8 mg every day
15-31 kg	5 mg every day	10 mg every day

**Usual Adjunctive Maintenance Dose for Epilepsy**

The usual maintenance doses identified in Tables 1 and 2 are derived from dosing regimens employed in the placebo-controlled adjunctive trials in which the efficacy of SUBVENTE was established. In patients receiving multi-drug regimens employing carbamazepine, phenytoin, phenobarbital, or primidone along with valproate, maintenance doses of adjunctive SUBVENTE as high as 700 mg/day have been used. In patients receiving valproate alone, maintenance doses of adjunctive SUBVENTE as high as 200 mg/day have been used. The advantage of using doses above those recommended in Tables 1 to 4 has not been established in controlled trials.

**2.3 Epilepsy Conversion from Adjunctive Therapy to Monotherapy**

The goal of the transition regimen is to attempt to maintain seizure control while mitigating the risk of serious rash associated with the rapid titration of SUBVENTE. The recommended maintenance dose of SUBVENTE as monotherapy is 500 mg/day given in 2 divided doses.

To avoid an increased risk of rash, the recommended initial dose and subsequent dose escalations for SUBVENTE should not be exceeded (see Boxed Warning).

**Conversion from Adjunctive Therapy with Carbamazepine, Phenytoin, Phenobarbital, or Primidone to Monotherapy with SUBVENTE**

After achieving a dose of 500 mg/day of SUBVENTE using the guidelines in Table 1, the concomitant enzyme-inducing AED should be withdrawn by 20% decrements each week over a 4-week period. The regimen for the withdrawal of the concomitant AED is based on experience gained in the controlled monotherapy clinical trial.

**Conversion from Adjunctive Therapy with Valproate to Monotherapy with SUBVENTE**

The conversion regimen involves the 4 steps outlined in Table 4.

**Table 4. Conversion from Adjunctive Therapy with Valproate to Monotherapy with SUBVENTE in Patients Aged 16 Years and Older with Epilepsy**

SUBVENTE	Valproate
Step 1: Achieve a dose of 200 mg/day according to guidelines in Table 1.	Maintain established stable dose.
Step 2: Maintain at 200 mg/day.	Increase dose by decrements no greater than 500 mg/day/week to 500 mg/day and then maintain for 1 week.
Step 3: Increase to 300 mg/day and maintain for 1 week.	Simultaneously decrease to 250 mg/day and maintain for 1 week.
Step 4: Increase by 100 mg/day every week to achieve maintenance dose of 500 mg/day.	Discontinue.

**Conversion from Adjunctive Therapy with Antiepileptic Drugs other than Carbamazepine, Phenytoin, Phenobarbital, Primidone, or Valproate to Monotherapy with SUBVENTE**

No specific dosing guidelines can be provided for conversion to monotherapy with SUBVENTE with AEDs other than carbamazepine, phenytoin, phenobarbital, primidone, or valproate.

**2.4 Bipolar Disorder**

The goal of maintenance treatment with SUBVENTE is to delay the time to occurrence of mood episodes (depression, mania, hypomania, mixed episodes) in patients treated for acute mood episodes with standard therapy (see Indications and Usage (2.1)). Patients taking SUBVENTE for more than 16 weeks should be periodically reassessed to determine the need for maintenance treatment.

**Adults**

The target dose of SUBVENTE is 200 mg/day (100 mg/day in patients taking valproate, which decreases the apparent clearance of lamotrigine, and 400 mg/day in patients not taking valproate and taking either carbamazepine, phenytoin, phenobarbital, primidone, or other drugs such as rifampin and the protease inhibitor lopinavir/ritonavir that increase the apparent clearance of lamotrigine). In the clinical trials, doses up to 400 mg/day as monotherapy were evaluated; however, no additional benefit was seen at 400 mg/day compared with 200 mg/day (see Clinical Studies (14.2)). Accordingly, doses above 200 mg/day are not recommended.

Treatment with SUBVENTE is introduced, based on concurrent medications, according to the regimen outlined in Table 5. If other psychotropic medications are withdrawn following stabilization, the dose of SUBVENTE should be adjusted. In patients discontinuing valproate, the dose of SUBVENTE should be doubled over a 2-week period in equal weekly increments (see Table 6). In patients discontinuing carbamazepine, phenytoin, phenobarbital, primidone, or other drugs such as rifampin and the protease inhibitors lopinavir/ritonavir and atazanavir/ritonavir that induce lamotrigine glucuronidation, the dose of SUBVENTE should remain constant for the first week, and then should be decreased by half over a 2-week period in equal weekly decrements (see Table 6). The dose of SUBVENTE may then be further adjusted to the target dose (200 mg) as clinically indicated.

If other drugs are subsequently introduced, the dose of SUBVENTE may need to be adjusted. In particular, the introduction of valproate requires reduction in the dose of SUBVENTE (see Drug Interactions (7), Clinical Pharmacology (12.3)).

To avoid an increased risk of rash, the recommended initial dose and subsequent dose escalations of SUBVENTE should not be exceeded (see Boxed Warning).

**Table 5. Escalation Regimen for SUBVENTE in Adults with Bipolar Disorder**

	In Patients TAKING Valproate <sup>a</sup> or Valproate <sup>b</sup>	In Patients NOT TAKING Carbamazepine, Phenytoin, Phenobarbital, Primidone <sup>c</sup> or Valproate <sup>a</sup>	In Patients TAKING Carbamazepine, Phenytoin, Phenobarbital, or Primidone <sup>c</sup> and NOT TAKING Valproate <sup>a</sup>
Weeks 1 and 2	25 mg every other day	25 mg daily	50 mg daily
Weeks 3 and 4	50 mg daily	50 mg daily	100 mg daily, in divided doses
Week 5	75 mg daily	75 mg daily	100 mg daily, in divided doses
Week 6	100 mg daily	100 mg daily	100 mg daily, in divided doses
Week 7	100 mg daily	100 mg daily	up to 400 mg daily, in divided doses

<sup>a</sup>Valproate has been shown to inhibit glucuronidation and decrease the apparent clearance of lamotrigine (see Drug Interactions (7), Clinical Pharmacology (12.3)).

<sup>b</sup>Drugs that induce lamotrigine glucuronidation and increase clearance, other than the specified AEDs, include estrogen-containing products, including oral contraceptives, rifampin, and the protease inhibitors lopinavir/ritonavir and atazanavir/ritonavir. Dosing recommendations for oral contraceptives and the protease inhibitor atazanavir/ritonavir can be found in General Dosing Considerations (see Dosage and Administration (2.1)). Patients on rifampin and the protease inhibitor lopinavir/ritonavir should follow the same dosing titration/maintenance regimen used with AEDs that induce glucuronidation and increase clearance (see Dosage and Administration (2.1), Drug Interactions (7), Clinical Pharmacology (12.3)).

**Table 6. Dosage Adjustments to SUBVENTE in Adults with Bipolar Disorder following Discontinuation of Psychotropic Medications**

	Discontinuation of Psychotropic Drugs (excluding Valproate <sup>a</sup> , Carbamazepine, Phenytoin, Phenobarbital, or Primidone <sup>b</sup> )	After Discontinuation of Valproate <sup>a</sup>		After Discontinuation of Carbamazepine, Phenytoin, Phenobarbital, or Primidone <sup>b</sup>	
		Current Dose of SUBVENTE (mg/day)	100	Current Dose of SUBVENTE (mg/day)	100
Week 1	Maintain current dose of SUBVENTE	100	400	100	400
Week 2	Maintain current dose of SUBVENTE	200	200	200	200
Week 3 onward	Maintain current dose of SUBVENTE	200	200	200	200

<sup>a</sup>Valproate has been shown to inhibit glucuronidation and decrease the apparent clearance of lamotrigine (see Drug Interactions (7), Clinical Pharmacology (12.3)).

<sup>b</sup>Drugs that induce lamotrigine glucuronidation and increase clearance, other than the specified AEDs, include estrogen-containing products, including oral contraceptives, rifampin, and the protease inhibitors lopinavir/ritonavir and atazanavir/ritonavir. Dosing recommendations for oral contraceptives and the protease inhibitor atazanavir/ritonavir can be found in General Dosing Considerations (see Dosage and Administration (2.1)). Patients on rifampin and the protease inhibitor lopinavir/ritonavir should follow the same dosing titration/maintenance regimen used with AEDs that induce glucuronidation and increase clearance (see Dosage and Administration (2.1), Drug Interactions (7), Clinical Pharmacology (12.3)).

**3 DOSAGE FORMS AND STRENGTHS**

**3.1 Tablets**

25 mg, white to off white, round shape, flat face beveled edge, uncoated tablets debossed with "2L" on one side and break line on other side.

100 mg, white to off white, round shape, flat face beveled edge, uncoated tablets debossed with "10LA" on one side and break line on other side.

150 mg, white to off white, round shape, flat face beveled edge, uncoated tablets debossed with "15LA" on one side and break line on other side.

200 mg, white to off white, round shape, flat face beveled edge, uncoated tablets debossed with "20LA" on one side and break line on other side.

**4 CONTRAINDICATIONS**

SUBVENTE is contraindicated in patients who have demonstrated hypersensitivity (e.g., rash, angioedema, acute urticaria, extensive pruritus, mucosal ulceration) to the drug or its ingredients (see Boxed Warning, Warnings and Precautions (5.1, 5.3)).

**5 WARNINGS AND PRECAUTIONS**

**5.1 Serious Skin Rashes (see Boxed Warning)**

## Pediatric Population

The incidence of serious rash associated with hospitalization and discontinuation of SUBVENTE in a prospectively followed cohort of pediatric patients (aged 2 to 17 years) is approximately 0.3% to 0.6%. One rash-related death was reported in a prospectively followed cohort of 1,983 pediatric patients (aged 2 to 16 years) with epilepsy taking SUBVENTE as adjunctive therapy. Additionally, there have been rare cases of toxic epidermal necrolysis (TEN) with and without permanent sequelae and/or death in U.S. and foreign postmarketing experience.

There is evidence that the inclusion of valproate in a multirug regimen increases the risk of serious, potentially life-threatening rash in pediatric patients. In pediatric patients who used valproate concomitantly for epilepsy, 1.2% (6 of 482) experienced a serious rash compared with 0.6% (6 of 952) patients not taking valproate.

## Adult Population

Serious rash associated with hospitalization and discontinuation of SUBVENTE occurred in 0.3% (11 of 3,348) of adult patients who received SUBVENTE in premarketing clinical trials of the bipolar and other mood disorders clinical trials, the rate of serious rash was 0.08% (1 of 1,233) of adult patients who received SUBVENTE as initial monotherapy and 0.13% (2 of 1,538) of adult patients who received SUBVENTE as adjunctive therapy. No fatalities occurred among these individuals. However, in worldwide postmarketing experience, rare cases of rash-related death have been reported, but their numbers are too few to permit a precise estimate of the rate.

Among the rashes leading to hospitalization were Stevens-Johnson syndrome, toxic epidermal necrolysis, angioedema, and those associated with multirug hypersensitivity (see Warnings and Precautions (5.3)).

## Risk Factors

### Concomitant Use of Valproate

There is evidence that the inclusion of valproate in a multirug regimen increases the risk of serious, potentially life-threatening rash in adults. Specifically, of 584 patients administered SUBVENTE with valproate in epilepsy clinical trials, 6 (1%) were hospitalized in association with rash; in contrast, 4 (0.16%) of 2,398 clinical trial patients and volunteers administered SUBVENTE in the absence of valproate were hospitalized.

### Patients with History of Allergy or Rash to Other Antiepileptic Drugs

The risk of rash may be increased in patients with a history of allergy or rash to other AEDs.

### Not Adhering to the Recommended Dosage

The risk of rash is increased by both exceeding the recommended initial dose of SUBVENTE and exceeding the recommended dose escalation for SUBVENTE.

### Patients with Genetic Variant Human Leukocyte Antigen (HLA-B\*15:02 Allele)

Retrospective case-control studies in patients of certain Asian ancestry (e.g., Han Chinese and Thai) suggest that the HLA-B\*15:02 allele is associated with an increased risk (approximately 2.3 times, higher of developing Stevens-Johnson syndrome/SJS/toxic epidermal necrolysis, (TEN) in patients using lamotrigine. The risks and benefits of therapy should be weighed when considering use of SUBVENTE in patients known to be positive for HLA-B\*15:02. Application of HLA genotyping as a screening tool has important limitations and must never substitute for appropriate clinical vigilance and patient management. Many HLA-B\*15:02-positive patients treated with SUBVENTE will not develop SJS/TEN or other hypersensitivity reactions, and these reactions can still occur in HLA-B\*15:02-negative patients of any ethnicity.

## 5.2 Hemophagocytic Lymphohistiocytosis

Hemophagocytic lymphohistiocytosis (HLH) has occurred in pediatric and adult patients taking SUBVENTE for various indications. HLH is a life-threatening syndrome of pathologic immune activation characterized by clinical signs and symptoms of extreme systemic inflammation. It is associated with high mortality rates if not recognized early and treated. Common findings include fever, hepatosplenomegaly, rash, lymphadenopathy, neurologic symptoms, cytopenias, high serum ferritin, hypertriglyceridemia, and liver function and coagulation abnormalities. In cases of HLH reported with SUBVENTE, patients have presented with signs of systemic inflammation (fever, rash, hepatosplenomegaly, and organ system dysfunction) and blood dyscrasias. Symptoms have been reported to occur within 8 to 24 days following the initiation of treatment. Patients who develop early manifestations of pathologic immune activation should be evaluated immediately, and a diagnosis of HLH should be considered. SUBVENTE should be discontinued if an alternative etiology for the signs or symptoms cannot be established.

## 5.3 Multirug Hypersensitivity Reactions and Organ Failure

Multirug hypersensitivity reactions, also known as drug reaction with eosinophilia and systemic symptoms (DRESS), have occurred with SUBVENTE. Some have been fatal or life threatening. DRESS typically, although not exclusively, presents with fever, rash, and/or lymphadenopathy in association with other organ system involvement, such as hepatitis, nephritis, hematologic abnormalities, myocarditis, or myositis, sometimes resembling an acute viral infection. Eosinophilia is often present. This disorder is variable in its expression, and other organ systems not listed here may be involved.

Fatalities associated with acute multirug failure and various degrees of hepatic failure have been reported in 2 of 3,736 adult patients and 4 of 2,435 pediatric patients who received SUBVENTE in epilepsy clinical trials. Rare fatalities from multirug failure have also been reported in postmarketing use.

Isolated liver failure without rash or involvement of other organs has also been reported with SUBVENTE.

It is important to note that early manifestations of hypersensitivity (e.g., fever, lymphadenopathy) may be present even though a rash is not evident. If such signs or symptoms are present, the patient should be evaluated immediately. SUBVENTE should be discontinued if an alternative etiology for the signs or symptoms cannot be established.

Prior to initiation of treatment with SUBVENTE, the patient should be instructed that a rash or other signs or symptoms of hypersensitivity (e.g., fever, lymphadenopathy) may herald a serious medical event and that the patient should report any such occurrence to a healthcare provider immediately.

## 5.4 Cardiac Rhythm and Conduction Abnormalities

In vitro testing showed that SUBVENTE exhibits class II antiarrhythmic activity at therapeutically relevant concentrations (see Clinical Pharmacology (12.2)). Based on these in vitro findings, SUBVENTE could slow ventricular conduction (normal QRS) and induce proarrhythmia, which can lead to sudden death, in patients with clinically important structural or functional heart disease (i.e., patients with heart failure, valvular heart disease, congenital heart disease, conduction system disease, ventricular arrhythmias, cardiac chemopathies [e.g., Brugada syndrome], clinically important ischemic heart disease, or multiple risk factors for coronary artery disease). Any expected or observed benefit of SUBVENTE in an individual patient with clinically important structural or functional heart disease must be carefully weighed against the risks for serious arrhythmias and/or death for that patient. Concomitant use of other sodium channel blockers may further increase the risk of proarrhythmia.

## 5.5 Blood Dyscrasias

There have been reports of blood dyscrasias that may or may not be associated with multirug hypersensitivity (also known as DRESS) (see Warnings and Precautions (5.3)). These have included neutropenia, leukopenia, anemia, thrombocytopenia, pancytopenia, and, rarely, aplastic anemia and pure red cell aplasia.

## 5.6 Suicidal Behavior and Ideation

Antiepileptic drugs, including SUBVENTE, increase the risk of suicidal thoughts or behavior in patients taking these drugs for any indication. Patients treated with any AED for any indication should be monitored for the emergence or worsening of depression, suicidal thoughts or behavior, and/or any unusual changes in mood or behavior.

Pooled analyses of 199 placebo-controlled clinical trials (monotherapy and adjunctive therapy) of 11 different AEDs showed that patients randomized to 1 of the AEDs had approximately twice the risk (adjusted Relative Risk 1.8, 95% CI 1.2, 2.7) of suicidal thinking or behavior compared with patients randomized to placebo. In these trials, which had a median treatment duration of 12 weeks, the estimated incidence of suicidal behavior or ideation among 27,863 AED-treated patients was 0.43%, compared with 0.24% among 16,029 placebo-treated patients, representing an increase of approximately 1 case of suicidal thinking or behavior for every 530 patients treated. There were 4 suicides in drug-treated patients in the trials and none in placebo-treated patients, but the number of events is too small to allow any conclusion about drug effect on suicide.

The increased risk of suicidal thoughts or behavior with AEDs was observed as early as 1 week after starting treatment with AEDs and persisted for the duration of treatment assessed. Because most trials included in the analysis did not extend beyond 24 weeks, the risk of suicidal thoughts or behavior beyond 24 weeks could not be assessed.

The risk of suicidal thoughts or behavior was generally consistent among drugs in the data analysis. The finding of increased risk with AEDs of varying mechanism of action and across a range of indications suggests that the risk applies to all AEDs used for any indication. The risk did not vary substantially by age (5 to 100 years) in the clinical trials analyzed.

Table 7 shows absolute and relative risk by indication for all evaluated AEDs.

Table 7. Risk by Indication for Antiepileptic Drugs in the Pooled Analysis

Indication	Placebo Patients with Events per 1,000 Patients	Drug Patients with Events per 1,000 Patients	Relative Risk: Incidence of Events in Drug Patients/Incidence in Placebo Patients	Risk Difference: Additional Drug Patients with Events per 1,000 Patients
Epilepsy	1.0	3.4	3.5	2.4
Psychiatric	1.0	5.7	5.7	4.7
Other	1.0	1.8	1.9	0.9
Total	2.4	4.3	1.8	1.9

The relative risk for suicidal thoughts or behavior was higher in clinical trials for epilepsy than in clinical trials for psychiatric or other conditions, but the absolute risk differences were similar for the epilepsy and psychiatric indications.

Anyone considering prescribing SUBVENTE or any other AED must balance the risk of suicidal thoughts or behavior with the risk of untreated illness. Epilepsy and many other illnesses for which AEDs are prescribed are themselves associated with morbidity and mortality and an increased risk of suicidal thoughts and behavior. Should suicidal thoughts and behavior emerge during treatment, the prescriber needs to consider whether the emergence of these symptoms in any given patient may be related to the illness being treated.

Patients, their caregivers, and families should be informed that AEDs increase the risk of suicidal thoughts and behavior and should be advised of the need to be alert for the emergence or worsening of the signs and symptoms of depression, any unusual changes in mood or behavior, the emergence of suicidal thoughts or suicidal behavior, or thoughts about self-harm. Behaviors of concern should be reported immediately to healthcare providers.

## 5.7 Aseptic Meningitis

Therapy with SUBVENTE increases the risk of developing aseptic meningitis. Because of the potential for serious outcomes of untreated meningitis due to other causes, patients should also be evaluated for other causes of meningitis and treated as appropriate. Post-marketing cases of aseptic meningitis have been reported in pediatric and adult patients taking SUBVENTE for various indications. Symptoms upon presentation have included headache, fever, nausea, vomiting, and nuchal rigidity. Rash, photophobia, myalgia, chills, altered consciousness, and somnolence were also noted in some cases. Symptoms have been reported to occur within 1 day to one and a half months following the initiation of treatment. In most cases, symptoms were reported to resolve after discontinuation of SUBVENTE. Re-exposure resulted in a rapid return of symptoms (from within 30 minutes to 1 day following re-initiation of treatment) that were frequently more severe. Some of the patients treated with SUBVENTE who developed aseptic meningitis had underlying diagnoses of systemic lupus erythematosus or other autoimmune diseases.

Cerebrospinal fluid (CSF) analyzed at the time of clinical presentation in reported cases was characterized by a mild to moderate pleocytosis, normal glucose levels, and mild to moderate increase in protein. CSF white blood cell count differentials showed a predominance of neutrophils in a majority of the cases, although a predominance of lymphocytes was reported in approximately one third of the cases. Some patients also had new onset of signs and symptoms of involvement of other organs (predominantly hepatic and renal involvement), which may suggest that in these cases the aseptic meningitis observed was part of a hypersensitivity reaction (see Warnings and Precautions (5.3)).

## 5.8 Potential Medication Errors

Medication errors involving SUBVENTE have occurred. In particular, the name SUBVENTE or lamotrigine can be confused with the names of other commonly used medications. Medication errors may also occur between the different formulations of SUBVENTE. To reduce the potential of medication errors, write and say SUBVENTE clearly. Decisions of the SUBVENTE can be found in the Medication Guide that accompanies the product to highlight the distinctive markings, colors, and shapes that serve to identify the different presentations of the drug and thus, may help reduce the risk of medication errors. To avoid the medication error of using the wrong drug or formulation, patients should be strongly advised to visually inspect their tablets to verify that they are SUBVENTE, as well as the correct formulation of SUBVENTE, each time they fill their prescription.

## 5.9 Concomitant Use with Estrogen-Containing Products, Including Oral Contraceptives

Some estrogen-containing oral contraceptives have been shown to decrease serum concentrations of lamotrigine (see Clinical Pharmacology (12.3)). Dose adjustments may be necessary in most patients who start or stop estrogen-containing oral contraceptives while taking SUBVENTE (see Dosage and Administration (2.1.1)). During the week of inactive hormone preparation (pill-free week) of oral contraceptive therapy, plasma lamotrigine levels are expected to rise, as much as doubling at the end of the

head. Adverse reactions consistent with elevated levels of lamotrigine, such as dizziness, ataxia, and diplopia, could occur. Other oral contraceptive and other estrogen-containing therapies (such as HRT) have not been studied, though they may primarily affect lamotrigine pharmacokinetic parameters.

#### 5.10 Withdrawal Seizures

As with other AEDs, SUBVENITE should not be abruptly discontinued. In patients with epilepsy there is a possibility of increasing seizure frequency. In clinical trials in adults with bipolar disorder, 2 patients experienced seizures shortly after abrupt withdrawal of SUBVENITE. Unless safety concerns require a more rapid withdrawal, the dose of SUBVENITE should be tapered over a period of at least 2 weeks (approximately 50% reduction per week) [see Dosage and Administration (2.1)].

#### 5.11 Status Epilepticus

Valid estimates of the incidence of treatment-emergent status epilepticus among patients treated with SUBVENITE are difficult to obtain because reporters participating in clinical trials did not all employ identical rules for identifying cases. At a minimum, 7 of 2,343 adult patients had episodes that could unequivocally be described as status epilepticus. In addition, a number of reports of variably defined episodes of seizure exacerbation (e.g., seizure clusters, seizure bursts) were made.

#### 5.12 Addition of SUBVENITE to a Multidrug Regimen that Includes Valproate

Because valproate reduces the clearance of lamotrigine, the dosage of SUBVENITE in the presence of valproate is less than half of that required in its absence [see Dosage and Administration (2.2, 2.3, 2.4); Drug Interactions (7)].

#### 5.13 Binding in the Eye and Other Melanin-Containing Tissues

Because lamotrigine binds to melanin, it could accumulate in melanin-rich tissues over time. This raises the possibility that lamotrigine may cause toxicity in these tissues after extended use. Although ophthalmologic testing was performed in 1 controlled clinical trial, the testing was inadequate to exclude subtle effects or injury occurring after long term exposure. Moreover, the capacity of available tests to detect potentially adverse consequences, if any, of lamotrigine's binding to melanin is unknown [see Clinical Pharmacology (12.2)].

Accordingly, although there are no specific recommendations for periodic ophthalmologic monitoring, prescribers should be aware of the possibility of long-term ophthalmologic effects.

#### 5.14 Laboratory Tests

##### Falsely Positive Drug Test Results

Lamotrigine has been reported to interfere with the assay used in some rapid urine drug screens, which can result in false-positive readings, particularly for phenylcyclidine (PCP). A more specific analytical method should be used to confirm a positive result.

##### Plasma Concentrations of Lamotrigine

The value of monitoring plasma concentrations of lamotrigine in patients treated with SUBVENITE has not been established. Because of the possible pharmacokinetic interactions between lamotrigine and other drugs, including AEDs (see Table 13), monitoring of the plasma levels of lamotrigine and concomitant drugs may be indicated, particularly during dosage adjustments. In general, clinical judgment should be exercised regarding monitoring of plasma levels of lamotrigine and other drugs and whether or not dosage adjustments are necessary.

## 6 ADVERSE REACTIONS

The following serious adverse reactions are described in more detail in the Warnings and Precautions section of the labeling:

- Serious Skin Rash [see Warnings and Precautions (5.1)]
- Hemophagocytic Lymphohistiocytosis [see Warnings and Precautions (5.2)]
- Multisystem Hypersensitivity Reactions and Organ Failure [see Warnings and Precautions (5.3)]
- Cardiac Rhythm and Conduction Abnormalities [see Warnings and Precautions (5.4)]
- Blood Dyscrasias [see Warnings and Precautions (5.5)]
- Suicidal Behavior and Ideation [see Warnings and Precautions (5.6)]
- Aseptic Meningitis [see Warnings and Precautions (5.7)]
- Withdrawal Seizures [see Warnings and Precautions (5.10)]
- Status Epilepticus [see Warnings and Precautions (5.11)]

### 6.1 Clinical Trial Experience

Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared with rates in the clinical trials of another drug and may not reflect the rates observed in practice.

#### Adults

**Most Common Adverse Reactions in All Clinical Trials: Adjunctive Therapy in Adults with Epilepsy.** The most commonly observed (≥5% for SUBVENITE and more common on drug than placebo) adverse reactions seen in association with SUBVENITE during adjunctive therapy in adults and not seen at an equivalent frequency among placebo-treated patients were dizziness, ataxia, somnolence, headache, diplopia, blurred vision, nausea, vomiting, and rash. Dizziness, diplopia, ataxia, blurred vision, nausea, and vomiting were dose related. Dizziness, diplopia, ataxia, and blurred vision occurred more commonly in patients receiving carbamazepine with SUBVENITE than in patients receiving other AEDs with SUBVENITE. Clinical data suggest a higher incidence of rash, including serious rash, in patients receiving concomitant valproate than in patients not receiving valproate [see Warnings and Precautions (5.1)].

Approximately 11% of the 3,378 adult patients who received SUBVENITE as adjunctive therapy in premarketing clinical trials discontinued treatment because of an adverse reaction. The adverse reactions most commonly associated with discontinuation were rash (3.0%), dizziness (2.8%), and headache (2.5%).

In a dose-response trial in adults, the rate of discontinuation of SUBVENITE for dizziness, ataxia, diplopia, blurred vision, nausea, and vomiting was dose related.

**Monotherapy in Adults with Epilepsy.** The most commonly observed (≥5% for SUBVENITE and more common on drug than placebo) adverse reactions seen in association with the use of SUBVENITE during the monotherapy phase of the controlled trial in adults not seen at an equivalent rate in the control group were vomiting, coordination abnormality, dyspepsia, nausea, dizziness, rhinitis, anxiety, insomnia, infection, pain, weight decrease, chest pain, and dyspareunia. The most commonly observed (≥5% for SUBVENITE and more common on drug than placebo) adverse reactions associated with the use of SUBVENITE during the conversion to monotherapy (add-on) period, not seen at an equivalent frequency among low-dose valproate-treated patients, were dizziness, headache, nausea, asthenia, coordination abnormality, vomiting, rash, somnolence, diplopia, ataxia, accidental injury, tremor, blurred vision, insomnia, nystagmus, diarrhea, lymphadenopathy, pruritus, and sinusitis.

Approximately 10% of the 420 adult patients who received SUBVENITE as monotherapy in premarketing clinical trials discontinued treatment because of an adverse reaction. The adverse reactions most commonly associated with discontinuation were rash (4.5%), headache (3.1%), and asthenia (2.4%).

**Adjunctive Therapy in Pediatric Patients with Epilepsy.** The most commonly observed (≥5% for SUBVENITE and more common on drug than placebo) adverse reactions seen in association with the use of SUBVENITE as adjunctive treatment in pediatric patients aged 2 to 16 years and not seen at an equivalent rate in the control group were infection, vomiting, rash, fever, somnolence, accidental injury, dizziness, diarrhea, abdominal pain, nausea, ataxia, tremor, asthenia, bronchitis, flu syndrome, and diplopia. In 339 patients aged 2 to 16 years with partial-onset seizures or generalized seizure of Lennox-Gastaut syndrome, 4.2% of patients on SUBVENITE and 2.9% of patients on placebo discontinued due to adverse reactions. The most commonly reported adverse reaction that led to discontinuation of SUBVENITE was rash.

Approximately 11.5% of the 1,081 pediatric patients aged 2 to 16 years who received SUBVENITE as adjunctive therapy in premarketing clinical trials discontinued treatment because of an adverse reaction. The adverse reactions most commonly associated with discontinuation were rash (4.4%), reaction aggravated (1.7%), and ataxia (0.6%).

**Controlled Adjunctive Clinical Trials in Adults with Epilepsy:** Table 8 lists adverse reactions that occurred in adult patients with epilepsy treated with SUBVENITE in placebo-controlled trials. In these trials, either SUBVENITE or placebo was added to the patient's current AED therapy.

Table 8. Adverse Reactions in Pooled, Placebo-Controlled Adjunctive Trials in Adult Patients with Epilepsy <sup>a,b</sup>

Body System/Adverse Reaction	Percent of Patients Receiving Adjunctive SUBVENITE (n = 711)	Percent of Patients Receiving Adjunctive Placebo (n = 419)
<b>Body as a whole</b>

Vaginitis	4	1
Menorrhagia	2	1

<sup>a</sup> Adverse reactions that occurred in at least 2% of patients treated with SUBVENITE and at a greater incidence than placebo. Patients in these adjunctive trials were receiving 1 to 3 of the concomitant AEDs: carbamazepine, phenytoin, phenobarbital, or primidone in addition to SUBVENITE or placebo. Patients may have reported multiple adverse reactions during the trial or at discontinuation; thus, patients may be included in more than 1 category.

In a randomized, parallel trial comparing placebo with 300 and 500 mg/day of SUBVENITE, some of the more common drug-related adverse reactions were dose related (see Table 9).

Table 9. Dose-Related Adverse Reactions from a Randomized, Placebo-Controlled, Adjunctive Trial in Adults with Epilepsy

Adverse Reaction	Percent of Patients Experiencing Adverse Reactions		
	Placebo (n = 73)	300 mg (n = 71)	500 mg (n = 72)
Ataxia	10	10	15
Blurred vision	10	11	25 <sup>a,b</sup>
Diplopia	8	24 <sup>a</sup>	49 <sup>a,b</sup>
Dizziness	27	31	54 <sup>a,b</sup>
Nausea	11	18	25 <sup>a</sup>
Vomiting	4	11	18 <sup>a</sup>

<sup>a</sup>Significantly greater than placebo group (P<0.05).

<sup>b</sup>Significantly greater than group receiving SUBVENITE 300 mg (P<0.05).

The overall adverse reaction profile for SUBVENITE was similar between females and males and was independent of age. Because the largest non-Caucasian racial subgroup was only 6% of patients exposed to SUBVENITE in placebo-controlled trials, there are insufficient data to support a statement regarding the distribution of adverse reaction reports by race. Generally, females receiving either SUBVENITE as adjunctive therapy or placebo were more likely to report adverse reactions than males. The only adverse reaction for which the reports on SUBVENITE were > 10% more frequent in females than males (without a corresponding difference by gender on placebo) was dizziness (difference = 16.3%). There was little difference between females and males in the rates of discontinuation of SUBVENITE for individual adverse reactions.

**Controlled Monotherapy Trial in Adults with Partial-Onset Seizures:** Table 10 lists adverse reactions that occurred in patients with epilepsy treated with monotherapy with SUBVENITE in a double-blind trial following discontinuation of other concomitant carbamazepine or phenytoin not seen at an equivalent frequency in the control group.

**Table 10. Adverse Reactions in a Controlled Monotherapy Trial in Adult Patients with Partial-Onset Seizures <sup>a,b</sup>**

Body System/Adverse Reaction	Percent of Patients Receiving SUBVENITE <sup>®</sup> as Monotherapy (n = 43)	Percent of Patients Receiving Low-Dose Valproate Monotherapy (n = 44)

 \* Up to 500 mg/day.  
 † 1,000 mg/day.

Adverse reactions that occurred with a frequency of < 5% and > 2% of patients receiving SUBVENITE and numerically more frequent than placebo were:  
 Body as a Whole: Asthenia, fever.  
 Digestive: Anorexia, dry mouth, rectal hemorrhage, peptic ulcer.

Metabolic and Nutritional: Peripheral edema.  
 Nervous System: Amnesia, ataxia, depression, hyperthermia, libido increase, decreased reflexes, increased reflexes, nystagmus, iritability, suicidal ideation.  
 Respiratory: Epistaxis, bronchitis, dyspnea.  
 Skin and Appendages: Contact dermatitis, dry skin, sweating.  
 Special Senses: Vision abnormality.

**Incidence in Controlled Adjunctive Trials in Pediatric Patients with Epilepsy:** Table 11 lists adverse reactions that occurred in 339 pediatric patients with partial-onset seizures or generalized seizures of Lennox-Gastaut syndrome who received SUBVENITE up to 15 mg/kg/day or a maximum of 750 mg/day.

**Table 11. Adverse Reactions in Pooled, Placebo-Controlled Adjunctive Trials in Pediatric Patients with Epilepsy <sup>a</sup>**

<sup>a</sup> Adverse reactions that occurred in at least 2% of patients treated with SUBVENITE and at a greater incidence than placebo.

**Bipolar Disorder in Adults**

The most common adverse reactions seen in association with the use of SUBVENITE as monotherapy (100 to 400 mg/day) in adult patients (aged 18 to 82 years) with bipolar disorder in the 2 double-blind, placebo-controlled trials of 18 months' duration are included in Table 12. Adverse reactions that occurred in at least 5% of patients and were numerically more frequent during the dose-escalation phase of SUBVENITE in these trials (when patients may have been receiving concomitant medications) compared with the monotherapy phase were: headache (25%), rash (11%), dizziness (10%), diarrhea (8%), dream abnormality (6%), and pruritus (6%).  
 During the monotherapy phase of the double-blind, placebo-controlled trials of 18 months' duration, 13% of 227 patients who received SUBVENITE (100 to 400 mg/day), 14% of 190 patients who received placebo, and 23% of 146 patients who received lithium discontinued therapy because of an adverse reaction. The adverse reactions that most commonly led to discontinuation of SUBVENITE were rash (3%) and mania/hypomania/mixed mood adverse reactions (2%). Approximately 16% of 2,401 patients who received SUBVENITE (50 to 500 mg/day) for bipolar disorder in premarketing trials discontinued therapy because of an adverse reaction, most commonly due to rash (15%) and mania/hypomania/mixed mood adverse reactions (2%).  
 The overall adverse reaction profile for SUBVENITE was similar between females and males, between elderly and nonelderly patients, and among racial groups.

**Table 12. Adverse Reactions in 2 Placebo-Controlled Trials in Adult Patients with Bipolar I Disorder <sup>a,b</sup>**

Body System/Adverse Reaction	Percent of Patients Receiving SUBVENITE (n = 227)	Percent of Patients Receiving Placebo (n = 190)
General		
Back pain	8	6
Fatigue	8	5
Abdominal pain	6	3
Digestive		
Nausea	14	11
Constipation	5	2
Vomiting	5	2
Nervous System		
Insomnia	10	6
Somnolence	9	7
Xerostomia (dry mouth)	6	4
Respiratory		
Rhinitis	7	4
Exacerbation of cough	5	3
Pharyngitis	5	4
Skin		
Rash (horseserous) <sup>c</sup>	7	5

<sup>a</sup> Adverse reactions that occurred in at least 5% of patients treated with SUBVENITE and at a greater incidence than placebo.  
<sup>b</sup> Patients in these trials were converted to SUBVENITE (100 to 400 mg/day) or placebo monotherapy from add-on therapy with other psychotropic medications. Patients may have reported multiple adverse reactions during the trial; thus, patients may be included in more than 1 category.  
<sup>c</sup> In the overall bipolar and other mood disorders clinical trials, the rate of serious rash was 0.05% (1 of 1,233) of adult patients who received SUBVENITE as initial monotherapy and 0.13% (2 of 1,538) of adult patients who received SUBVENITE as adjunctive therapy (see Warnings and Precautions (5.1)).  
 Other reactions that occurred in 5% or more patients but equally or more frequently in the placebo group included: dizziness, mania, headache, infection, influenza, pain, accidental injury, diarrhea, and dyspepsia.

Adverse reactions that occurred with a frequency of < 5% and > 1% of patients receiving SUBVENITE and numerically more frequent than placebo were:  
 General: Fever, neck pain.  
 Cardiovascular: Migraine.  
 Digestive: Flatulence.  
 Metabolic and Nutritional: Weight gain, edema.

Musculoskeletal: Arthralgia, myalgia.  
 Nervous System: Amnesia, depression, agitation, emotional lability, dyspraxia, abnormal thoughts, dream abnormality, hypoaesthesia.  
 Respiratory: Sinusitis.  
 Urogenital: Urinary frequency.

**Adverse Reactions following Abrupt Discontinuation:** In the 2 controlled clinical trials, there was no increase in the incidence, severity, or type of adverse reactions in patients with bipolar disorder after abruptly terminating therapy with SUBVENITE. In the clinical development program in adults with bipolar disorder, 2 patients experienced seizures shortly after abrupt withdrawal of SUBVENITE. (See Warnings and Precautions (5.10)).  
**Mania/Hypomania/Mixed Episodes:** During the double-blind, placebo-controlled clinical trials in bipolar I disorder in which adults were converted to monotherapy with SUBVENITE (100 to 400 mg/day) from other psychotropic medications and followed for up to 18 months, the rates of manic or hypomanic or mixed mood episodes reported as adverse reactions were 5% for patients treated with SUBVENITE (n = 227), 4% for patients treated with lithium (n = 186), and 7% for patients treated with placebo (n = 190). In all bipolar controlled trials combined, adverse reactions of mania (including hypomania and mixed mood episodes) were reported in 5% of patients treated with SUBVENITE (n = 956), 3% of patients treated with lithium (n = 280), and 4% of patients treated with placebo (n = 803).

**6.2 Other Adverse Reactions Observed in All Clinical Trials**

SUBVENITE has been administered to 6,694 individuals for whom complete adverse reaction data was captured during all clinical trials, only some of which were placebo controlled. During these trials, all adverse reactions were recorded by the clinical investigators using terminology of their own choosing. To provide a meaningful estimate of the proportion of individuals having adverse reactions, similar types of adverse reactions were grouped into a smaller number of standardized categories using modified COSTART dictionary terminology. The frequencies presented represent the proportion of the 6,694 individuals exposed to SUBVENITE who experienced an event of the type cited on at least 1 occasion while receiving SUBVENITE. All reported adverse reactions are included except those already listed in the previous tables or elsewhere in the labeling, those too general to be informative, and those not reasonably associated with the use of the drug.

Adverse reactions are further classified within body system categories and enumerated in order of decreasing frequency using the following definitions: frequent adverse reactions are defined as those occurring in at least 1/100 patients; infrequent adverse reactions are those occurring in 1/100 to 1/1,000 patients; rare adverse reactions are those occurring in fewer than 1/1,000 patients.

**Body as a Whole:**  
 Infrequent: Allergic reaction, chills, malaise.  
**Cardiovascular System:**  
 Infrequent: Flushing, hot flashes, hypertension, palpitations, postural hypotension, syncope, tachycardia, vasodilation.  
**Dermatological:**

Inrequent: Acne, alopecia, hirsutism, maculopapular rash, skin discoloration, urticaria.

Rare: Angioedema, erythema, exfoliative dermatitis, fungal dermatitis, herpes zoster, leukoderma, multiforme erythema, petechial rash, pustular rash, Stevens-Johnson syndrome, vesiculobullous rash.

**Digestive System**

Inrequent: Dysphagia, eructation, gastritis, gingivitis, increased appetite, increased salivation, liver function tests: abnormal, mouth ulceration.

Rare: Gastrointestinal hemorrhage, glossitis, gum hemorrhage, gum hyperplasia, hematemesis, hemorrhagic colitis, hepatitis, melena, stomach ulcer, stomatitis, tongue edema.

**Endocrine System**

Rare: Goiter, hypothyroidism.

**Hematologic and Lymphatic System**

Inrequent: Ecchymosis, leukopenia.

Rare: Anemia, eosinophilia, fibrin decrease, fibrinogen decrease, iron deficiency anemia, leukocytosis, lymphocytosis, macrocytic anemia, pancytopenia, thrombocytopenia.

**Metabolic and Nutritional Disorders**

Inrequent: Aspartate transaminase increased.

Rare: Alcohol intolerance, alkaline phosphatase increase, alanine transaminase increase, bilirubinemia, general edema, gamma-glutamyl transpeptidase increase, hyperglycemia.

**Musculoskeletal System**

Inrequent: Arthritis, leg cramps, myasthenia, twitching.

Rare: Bursitis, muscle atrophy, pathological fracture, tendinous contracture.

**Neurologic System**

Frequent: Confusion, paresthesia.

Inrequent: Akathisia, apathy, aphasia, central nervous system depression, depersonalization, dysarthria, dyskinesia, euphoria, hallucinations, hostility, hyperkinesia, hypernesia, libido decreased, memory decrease, mixed racing, movement disorder, myoclonus, panic attack, paranoid reaction, personality disorder, psychosis, sleep disorder, stupor, suicidal ideation.

Rare: Choreoathetosis, delirium, delusions, dysphoria, dystonia, extrapyramidal syndrome, faintness, grand mal convulsions, hemiplegia, hyperalgesia, hyperesthesia, hypoleptosis, hypotonia, manic depression reaction, muscle spasm, neuralgia, neuronitis, paralysis, peripheral neuritis.

**Respiratory System**

Inrequent: Tachypnea.

Rare: Hiccups, hyperventilation.

**Special Senses**

Frequent: Amblyopia.

Inrequent: Abnormality of accommodation, conjunctivitis, dry eyes, ear pain, photophobia, taste perversion, tinnitus.

Rare: Deafness, lacrimation disorder, oscillopsia, parosmia, ptosis, strabismus, taste loss, vertigo, visual field defect.

**Urogenital System**

Inrequent: Abnormal ejaculation, hematuria, impotence, menorrhagia, polyuria, urinary incontinence.

Rare: Acute kidney failure, anorgasmia, breast abscess, breast neoplasm, creatinine increase, cystitis, dysuria, epididymitis, female betadine, kidney failure, kidney pain, nocturia, urinary retention, urinary urgency.

**6.3 Postmarketing Experience**

The following adverse reactions have been identified during postapproval use of SUBVENITE. Because these reactions are reported voluntarily from a population of uncertain size, it is not always possible to reliably estimate their frequency or establish a causal relationship to drug exposure.

**Blood and Lymphatic**

Agranulocytosis, hemolytic anemia, lymphadenopathy not associated with hypersensitivity disorder, pseudolymphoma.

**Gastrointestinal**

Esophagitis.

**Hepatobiliary Tract and Pancreas**

Pancreatitis.

**Immunologic**

Hypogammaglobulinemia, lupus-like reaction, vasculitis.

**Lower Respiratory**

Apnea.

**Musculoskeletal**

Rhabdomyolysis has been observed in patients experiencing hypersensitivity reactions.

**Neurologic System**

Aggression, exacerbation of Parkinsonian symptoms in patients with pre-existing Parkinson's disease, tics.

**Non-site Specific**

Progressive immunosuppression.

**Renal and Urinary Disorders**

Tubulointerstitial nephritis (has been reported alone and in association with ulcers).

**Skin and Subcutaneous Tissue Disorders**

Photosensitivity reaction.

**7 DRUG INTERACTIONS**

Significant drug interactions with SUBVENITE are summarized in this section. Urinary 5'-diphospho-glucuronyl transferases (UGT) have been identified as the enzymes responsible for metabolism of lamotrigine. Drugs that induce or inhibit glucuronidation may, therefore, affect the apparent clearance of lamotrigine. Strong or moderate inducers of the cytochrome P450 3A4 (CYP3A4) enzyme, which are also known to induce UGT, may also enhance the metabolism of lamotrigine.

Those drugs that have been demonstrated to have a clinically significant impact on lamotrigine metabolism are outlined in Table 13. Specific dosing guidance for these drugs is provided in the Dosage and Administration section, and, for women taking estrogen-containing products, including oral contraceptives, in the Warnings and Precautions section (see Dosage and Administration (2.1), Warnings and Precautions (5.3)). Additional details of these drug interaction studies are provided in the Clinical Pharmacology section (see Clinical Pharmacology (12.3)).

Table 13. Established and Other Potentially Significant Drug Interactions

Concomitant Drug	Effect on Concentration of Lamotrigine or Concomitant Drug	Clinical Comment
Lamotrigine containing oral contraceptive preparations containing 30 mcg ethinyl estradiol and 150 mcg levonorgestrel	↓ lamotrigine ↓ levonorgestrel	Decreased lamotrigine concentrations approximately 50%. Decrease in levonorgestrel component by 19%.
Carbamazepine and carbamazepine epoxide	↓ lamotrigine ↓ carbamazepine epoxide	Addition of carbamazepine decreases lamotrigine concentration approximately 40%. May increase carbamazepine epoxide levels.
Levodopa/ritonavir	↓ lamotrigine	Decreased lamotrigine concentration approximately 50%.
Azaxone/ritonavir	↓ lamotrigine	Decreased lamotrigine AUC approximately 32%.
Phenobarbital/primidone	↓ lamotrigine	Decreased lamotrigine concentration approximately 40%.
Phenytoin	↓ lamotrigine	Decreased lamotrigine concentration approximately 45%.
Rifampin	↓ lamotrigine	Decreased lamotrigine AUC approximately 40%.
Valproate	↑ lamotrigine ↑ valproate	Increased lamotrigine concentrations slightly more than 2-fold. There are conflicting study results regarding effect of lamotrigine on valproate concentrations: 1) a mean 25% decrease in valproate concentrations in healthy volunteers, 2) no change in valproate concentrations in controlled clinical trials in patients with epilepsy.

↓ = decreased lamotrigine glucuronidation  
↑ = increased (inhibits lamotrigine glucuronidation)  
↔ = conflicting data.

**Effect of SUBVENITE on Organic Cationic Transporter 2 Substrates**

Lamotrigine is an inhibitor of renal tubular secretion via organic cationic transporter 2 (OCT2) proteins (see Clinical Pharmacology (12.3)). This may result in increased plasma levels of certain drugs that are substantially excreted via this route. Coadministration of SUBVENITE with OCT2 substrates with a narrow therapeutic index (e.g., dofetilide) is not recommended.

**8 USE IN SPECIFIC POPULATIONS**

**8.1 Pregnancy**

**Pregnancy Exposure Registry**

There is a pregnancy exposure registry that monitors pregnancy outcomes in women exposed to AEDs, including SUBVENITE, during pregnancy. Encourage women who are taking SUBVENITE during pregnancy to enroll in the North American Antiepileptic Drug (NAAED) Pregnancy Registry by calling 1-888-233-2334 or visiting <http://www.aedpregnancyregistry.org/>.

**Risk Summary**

Data from several prospective pregnancy exposure registries and epidemiological studies of pregnant women have not detected an increased frequency of major congenital malformations or a consistent pattern of malformations among women exposed to lamotrigine compared with the general population (see Data). The majority of SUBVENITE pregnancy exposure data are from women with epilepsy. In animal studies, administration of lamotrigine during pregnancy resulted in developmental toxicity (increased mortality, decreased body weights, increased structural variation, neurobehavioral abnormalities) at doses lower than those administered clinically.

Lamotrigine decreased fetal folate concentrations in rats, an effect known to be associated with adverse pregnancy outcomes in animals and humans (see Data).

In the U.S. general population, the estimated background risk of major birth defects and miscarriage in clinically recognized pregnancies is 2% to 4% and 13% to 20%, respectively.

**Clinical Considerations**

**Disease-associated Maternal and/or Embryofetal Risk**

Epilepsy, with or without exposure to antiepileptic drugs, has been associated with several adverse outcomes during pregnancy, including preterm labor, antepartum and postpartum hemorrhage, placental abruption, poor fetal growth, prematurity, fetal death, and maternal mortality. The risk of minor or fetal injury may be greatest for patients with untreated or poorly controlled convulsive seizures. Women with epilepsy who become pregnant should not abruptly discontinue antiepileptic drugs, including SUBVENITE, due to the risk of status epilepticus or severe seizures, which may be life-threatening (see Warnings and Precautions (5.10)).

**Dose Adjustments During Pregnancy and the Postpartum Period**

As with other AEDs, physiological changes during pregnancy may affect lamotrigine concentrations and/or therapeutic effect. There have been reports of decreased lamotrigine concentrations during pregnancy and restoration of pre-pregnancy concentrations after delivery. Dose adjustments may be necessary to maintain clinical response.

**Data**

**Human Data:** Data from several international pregnancy registries have not shown an increased risk for malformations overall. The International Lamotrigine Pregnancy Registry reported major congenital malformations in 2.2% (95% CI: 1.6%, 3.1%) of 1,558 infants exposed to lamotrigine monotherapy in the first trimester of pregnancy. The NAAED Pregnancy Registry reported major congenital malformations among 2.0% of 1,562 infants exposed to lamotrigine monotherapy in the first trimester. LUMAP, a large international pregnancy registry focused outside of North America, reported major birth defects in 2.9% (95% CI: 2.3%, 3.7%) of 2,514 exposures to lamotrigine monotherapy in the first trimester. The frequency of major congenital malformations was similar to estimates from the general population.

The NAAED Pregnancy Registry observed an increased risk of isolated oral clefts among 2,200 infants exposed to lamotrigine early in pregnancy, the risk of oral clefts was 3.2 per 1,000 (95% CI: 1.4, 6.3), a 3-fold increased risk versus unexposed healthy controls. This finding has not been observed in other large international pregnancy registries. Furthermore, a case-control study based on 21 congenital anomaly registries covering over 10 million births in Europe reported an adjusted odds ratio for isolated oral clefts with lamotrigine exposure of 1.45 (95% CI: 0.8, 2.63).

Several meta-analyses have not reported an increased risk of major congenital malformations following lamotrigine exposure in pregnancy compared with healthy and disease-matched controls. No patterns of specific malformation types were observed.

The same meta-analyses evaluated the risk of additional maternal and infant outcomes including fetal death, stillbirth, preterm birth, small for gestational age, and neurodevelopmental delay. Although there are no data suggesting an increased risk of these outcomes with lamotrigine monotherapy exposure, differences in outcome definition, ascertainment methods, and comparator groups limit the conclusions that can be drawn.

**Animal Data:** When lamotrigine was administered to pregnant mice, rats, or rabbits during the period of organogenesis (oral doses of up to 125, 25, and 30 mg/kg, respectively), reduced fetal body weight and increased incidences of fetal skeletal variations were seen in mice and rats at doses that were also maternally toxic. The no-effect doses for embryofetal developmental toxicity in mice, rats, and rabbits (75, 6.25, and 30 mg/kg, respectively) are similar to (mice and rabbits) or less than (rats) the human dose of 400 mg/day on a body surface area (mg/m<sup>2</sup>) basis.

In a study in which pregnant rats were administered lamotrigine (oral doses of 0, 5, or 25 mg/kg) during the period of organogenesis and offspring were evaluated postnatally, neurobehavioral abnormalities were observed in exposed offspring at both doses. The lowest effect dose for developmental neurotoxicity in rats is less than the human dose of 400 mg/day on a mg/m<sup>2</sup> basis. Maternal toxicity was observed at the higher dose tested.

When pregnant rats were administered lamotrigine (oral doses of 0, 5, 10, or 20 mg/kg) during the latter part of gestation and throughout lactation, increased offspring mortality (including stillbirths) was seen at all doses. The lowest effect dose for pre- and post-natal developmental toxicity in rats is less than the human dose of 400 mg/day on a mg/m<sup>2</sup> basis. Maternal toxicity was observed at the 2 highest doses tested.

When administered to pregnant rats, lamotrigine decreased fetal foetal concentrations at doses greater than or equal to 5 mg/kg/day, which is less than the human dose of 400 mg/day on a mg/m<sup>2</sup> basis.

## 8.2 Lactation

### Back Summary

Lamotrigine is present in milk from lactating women taking SUBVENITE (see Data). Neonates and young infants are at risk for high serum levels because maternal serum and milk levels can rise to high levels postpartum if lamotrigine dosage has been increased during pregnancy but is not reduced after delivery to the pre-pregnancy dosage. Glucuronidation is required for drug clearance. Glucuronidation capacity is immature in the infant and this may also contribute to the level of lamotrigine exposure. Events including rash, apnea, drowsiness, poor sucking, and poor weight gain (requiring hospitalization in some cases) have been reported in infants who have been human milk-fed by mothers using lamotrigine; whether or not these events were caused by lamotrigine is unknown. No data are available on the effects of the drug on milk production.

The developmental and health benefits of breastfeeding should be considered along with the mother's clinical need for SUBVENITE and any potential adverse effects on the breastfed infant from SUBVENITE or from the underlying maternal condition.

### Clinical Considerations

Human milk-fed infants should be closely monitored for adverse events resulting from lamotrigine. Measurement of infant serum levels should be performed to rule out toxicity concerns arise. Human milk-feeding should be discontinued in infants with lamotrigine toxicity.

### Data

Data from multiple small studies indicate that lamotrigine plasma levels in nursing infants have been reported to be as high as 50% of maternal plasma concentrations.

## 8.4 Pediatric Use

### Efficacy

SUBVENITE is indicated as adjunctive therapy in patients aged 2 years and older for partial-onset seizures, the generalized seizures of Lennox-Gastaut syndrome, and PGTC seizures.

Safety and efficacy of SUBVENITE used as adjunctive treatment for partial onset seizures were not demonstrated in a small, randomized, double-blind, placebo-controlled withdrawal trial in very young pediatric patients (aged 1 to 24 months). SUBVENITE was associated with an increased risk for infectious adverse reactions (SUBVENITE 37%, placebo 5%), and respiratory adverse reactions (SUBVENITE 26%, placebo 9%). Infectious adverse reactions included bronchitis, bronchiolitis, ear infection, eye infection, otitis externa, pharyngitis, urinary tract infection, and viral infection. Respiratory adverse reactions included nasal congestion, cough, and sneeze.

### Bipolar Disorder

Safety and efficacy of SUBVENITE for the maintenance treatment of bipolar disorder were not established in a double-blind, randomized withdrawal, placebo-controlled trial that evaluated 301 pediatric patients aged 10 to 17 years with a current, manic/hypomanic, depressed, or mixed mood episode as defined by DSM-IV-TR. In the randomized phase of the trial, adverse reactions that occurred in at least 5% of patients taking SUBVENITE (n = 87) and were twice as common compared with patients taking placebo (n = 80) were influenza (SUBVENITE 8%, placebo 2%), oropharyngeal pain (SUBVENITE 8%, placebo 2%), vomiting (SUBVENITE 6%, placebo 2%), contact dermatitis (SUBVENITE 5%, placebo 2%), upper abdominal pain (SUBVENITE 5%, placebo 1%), and suicidal ideation (SUBVENITE 5%, placebo 0%).

### Juvenile Animal Data

In a juvenile animal study in which lamotrigine (oral doses of 0, 5, 15, or 30 mg/kg) was administered to young rats from postnatal day 7 to 62, decreased viability and growth were seen at the highest dose tested and long-term neurobehavioral abnormalities (decreased locomotor activity, increased reactivity, and learning deficits in animals tested as adults) were observed at the 2 highest doses. The no-effect dose for adverse developmental effects in juvenile animals is less than the human dose of 400 mg/day on a mg/m<sup>2</sup> basis.

## 8.5 Geriatric Use

Clinical trials of SUBVENITE for epilepsy and bipolar disorder did not include sufficient numbers of patients aged 65 years and older to determine whether they respond differently from younger patients or exhibit a different safety profile than that of younger patients. In general, dose selection for an elderly patient should be cautious, usually starting at the low end of the dosing range, reflecting the greater frequency of decreased hepatic, renal, or cardiac function and of concomitant disease or other drug therapy.

## 8.6 Hepatic Impairment

Experience in patients with hepatic impairment is limited. Based on a clinical pharmacology study in 24 subjects with mild, moderate, and severe liver impairment, the following general recommendations can be made (see *Clinical Pharmacology* (12.3)). No dosage adjustment is needed in patients with mild liver impairment. Initial, escalation, and maintenance doses should generally be reduced by approximately 25% in patients with moderate and severe liver impairment without acetate and 50% in patients with severe liver impairment with acetate. Escalation and maintenance doses may be adjusted according to clinical response (see *Dosage and Administration* (2.1)).

## 8.7 Renal Impairment

Lamotrigine is metabolized mainly by glucuronic acid conjugation, with the majority of the metabolites being recovered in the urine. In a small study comparing a single dose of lamotrigine in subjects with varying degrees of renal impairment with healthy volunteers, the plasma half-life of lamotrigine was approximately twice as long in the subjects with chronic renal failure (see *Clinical Pharmacology* (12.3)).

Initial doses of SUBVENITE should be based on patients' AED regimen; reduced maintenance doses may be effective for patients with significant renal impairment. Few patients with severe renal impairment have been evaluated during chronic treatment with lamotrigine. Because there is inadequate experience in this population, SUBVENITE should be used with caution in these patients (see *Dosage and Administration* (2.1)).

## 10 OVERDOSAGE

### 10.1 Human Overdose Experience

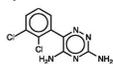

Overdoses involving quantities up to 15 g have been reported for SUBVENITE, some of which have been fatal. Overdose has resulted in ataxia, myasthenia, seizures (including tonic-clonic seizures), decreased level of consciousness, coma, and intraventricular conduction delay.

### 10.2 Management of Overdose

There are no specific antidotes for lamotrigine. Following a suspected overdose, hospitalization of the patient is advised. General supportive care is indicated, including frequent monitoring of vital signs and close observation of the patient. If indicated, emesis should be induced; usual precautions should be taken to protect the airway. It should be kept in mind that immediate-release lamotrigine is rapidly absorbed (see *Clinical Pharmacology* (12.3)). It is uncertain whether hemodialysis is an effective means of removing lamotrigine from the blood. In 6 renal failure patients, about 20% of the amount of lamotrigine in the body was removed by hemodialysis during a 4-hour session. A Poison Control Center should be contacted for information on the management of overdose of SUBVENITE.

## 11 DESCRIPTION

Lamotrigine, USP an AED of the phenyltriazine class, is chemically unrelated to existing AEDs. Lamotrigine's chemical name is 3,5-diamino-6-(2,3-dichlorophenyl)-as-triazine. Its molecular formula is C<sub>11</sub>H<sub>7</sub>N<sub>5</sub> and its molecular weight is 246.09. Lamotrigine, USP is a white to pale cream-colored powder and has a pK<sub>a</sub> of 5.7. Lamotrigine, USP is very slightly soluble in water (0.17 mg/mL at 25°C) and slightly soluble in 0.1 M HCl (4.1 mg/mL at 25°C). The structural formula is:

SUBVENITE (lamotrigine) tablets, USP are supplied for oral administration as 25-mg (white to off white), 100-mg (white to off white), 150-mg (white to off white), and 200-mg (white to off white) tablets. Each tablet contains the labeled amount of lamotrigine, USP and the following inactive ingredients: lactose monohydrate, magnesium stearate, microcrystalline cellulose, povidone, and sodium starch glycolate.

### Meets USP Dissolution Test 3

## 12 CLINICAL PHARMACOLOGY

### 12.1 Mechanism of Action

The precise mechanism(s) by which lamotrigine exerts its anticonvulsant action are unknown. In animal models designed to detect anticonvulsant activity, lamotrigine was effective in preventing seizure spread in the maximum electroshock (MES) and pentylenetetrazol (scMet) tests, and prevented seizures in the visually and electrically evoked after-discharge (EAD) tests for antiepileptic activity. Lamotrigine also displayed inhibitory properties in the kindling model in rats both during kindling development and in the fully kindled state. The relevance of these models to human epilepsy, however, is not known.

One proposed mechanism of action of lamotrigine, the relevance of which remains to be established in humans, involves an effect on sodium channels. In vitro pharmacological studies suggest that lamotrigine inhibits voltage-sensitive sodium channels, thereby stabilizing neuronal membranes and consequently modulating presynaptic transmitter release of excitatory amino acids (e.g., glutamate and aspartate).

### Effect of Lamotrigine on N-Methyl-D-Aspartate Receptor-Mediated Activity

Lamotrigine did not inhibit N-methyl-D-aspartate (NMDA)-induced depolarizations in rat cortical slices or NMDA-induced cyclic GMP formation in membrane rat cerebellum, nor did lamotrigine displace compounds that are either competitive or noncompetitive ligands at the glutamate receptor complex (NMDA, CGS, YDAP). The IC<sub>50</sub> for lamotrigine effects on NMDA-induced currents (in the presence of 3 μM of glycine) in cultured hippocampal neurons exceeded 100 μM.

The mechanisms by which lamotrigine exerts its therapeutic action in bipolar disorder have not been established.

### 12.2 Pharmacodynamics

#### Folate Metabolism

In vitro, lamotrigine inhibited dihydrofolate reductase, the enzyme that catalyzes the reduction of dihydrofolate to tetrahydrofolate. Inhibition of this enzyme may interfere with the biosynthesis of nucleic acids and proteins. When oral daily doses of lamotrigine were given to pregnant rats during organogenesis, fetal, placental, and maternal folate concentrations were reduced. Significantly reduced concentrations of folate are associated with teratogenesis (see *Use in Specific Populations* (8.1)). Folate concentrations were also reduced in male rats given repeated oral doses of lamotrigine. Reduced concentrations were partially returned to normal when supplemented with folic acid.

#### Cardiac Electrophysiology

Effect of Lamotrigine: In vitro studies show that lamotrigine exhibits Class IB antiarrhythmic activity at therapeutically relevant concentrations. It blocks human cardiac sodium channels with rapid onset and offset kinetics and strong voltage dependence, consistent with other Class IB antiarrhythmic agents. At therapeutic doses, SUBVENITE did not slow ventricular conduction (widen QRS) in healthy individuals in a thorough QT study; however, in patients with clinically important structural or functional heart disease (i.e., patients with heart failure, valvular heart disease, congenital heart disease, conduction system disease, ventricular arrhythmias, cardiac channelopathies [e.g., Brugada syndrome], clinically important ischemic heart disease, or multiple risk factors for coronary artery disease), SUBVENITE could slow ventricular conduction (widen QRS) and induce proarrhythmia, which can lead to sudden death. Elevated heart rates could also increase the risk of ventricular conduction slowing with SUBVENITE.

Effect of Lamotrigine Metabolite: In dogs, lamotrigine is extensively metabolized to a 2-N

methyl metabolite. This metabolite causes dose-dependent prolongation of the PR interval, widening of the QRS complex, and, at higher doses, complete AV conduction block. The in vitro electrophysiological effects of this metabolite have not been studied. Similar cardiovascular effects from this metabolite are not anticipated in humans because only trace amounts of the 2-N-methyl metabolite (<0.6% of lamotrigine dose) have been found in human urine (see Clinical Pharmacology (7.2)). However, it is conceivable that plasma concentrations of this metabolite could be increased in patients with a reduced capacity to glucuronidate lamotrigine (e.g., in patients with liver disease, patients taking concomitant medications that inhibit glucuronidation).

#### Accumulation in Kidneys

Lamotrigine accumulated in the kidney of the male rat, causing chronic progressive nephrosis, necrosis, and mineralization. These findings are attributed to a 2-microglobulin, a species- and sex-specific protein that has not been detected in humans or other animal species.

#### Melanin Binding

Lamotrigine binds to melanin-containing tissues, e.g., in the eye and pigmented skin. It has been found in the eyelid tract up to 52 weeks after a single dose in rodents.

#### 12.3 Pharmacokinetics

The pharmacokinetics of lamotrigine have been studied in subjects with epilepsy, healthy young and elderly volunteers, and volunteers with chronic renal failure. Lamotrigine pharmacokinetic parameters for adult and pediatric subjects and healthy normal volunteers are summarized in Tables 14 and 16.

Table 14. Mean Pharmacokinetic Parameters\* in Healthy Volunteers and Adult Subjects with Epilepsy

Adult Study Population	Number of Subjects	Time of Maximum Plasma Concentration (h) <sub>1/2, T<sub>max</sub></sub>	Elimination Half-life (h) <sub>1/2, t<sub>1/2</sub></sub>	CL/F: Apparent Plasma Clearance (mL/min/kg)
<b>Healthy volunteers taking no other medications:</b> Single-dose SUBVENTE	179	2.2 (0.25 to 12.0)	32.8 (14.0 to 103.0)	0.44 (0.12 to 1.10)
Multiple-dose SUBVENTE	36	1.7 (0.2 to 4.0)	25.4 (11.6 to 61.6)	0.58 (0.24 to 1.15)
<b>Healthy volunteers taking valproate:</b> Single-dose SUBVENTE				
Multiple-dose SUBVENTE	6	1.8 (1.0 to 4.0)	48.3 (31.5 to 88.6)	0.30 (0.14 to 0.42)
Single-dose SUBVENTE	18	1.9 (0.5 to 3.5)	70.3 (41.9 to 113.5)	0.18 (0.12 to 0.33)
<b>Subjects with epilepsy taking valproate only:</b> Single-dose SUBVENTE	4	4.8 (1.8 to 8.4)	58.8 (30.5 to 88.8)	0.29 (0.16 to 0.40)
<b>Subjects with epilepsy taking carbamazepine, phenytoin, phenobarbital, or primidone plus valproate:</b> Single-dose SUBVENTE	25	3.8 (1.0 to 10.0)	27.2 (13.2 to 51.6)	0.53 (0.27 to 1.04)
<b>Subjects with epilepsy taking carbamazepine, phenytoin, phenobarbital, or primidone<sup>†</sup>:</b> Single-dose SUBVENTE	24	2.3 (0.5 to 5.0)	14.4 (6.4 to 30.4)	1.10 (0.51 to 2.22)
Multiple-dose SUBVENTE	17	2.0 (0.75 to 5.93)	12.6 (7.5 to 23.1)	1.21 (0.62 to 1.82)

\*The majority of parameter means determined in each study had coefficients of variation between 20% and 40% for half-life and CL/F and between 30% and 70% for T<sub>max</sub>. The overall mean values were calculated from individual study means that were weighted based on the number of volunteers/subjects in each study. The numbers in parentheses below each parameter mean represent the range of individual volunteer/subject values across studies.

<sup>†</sup>Carbamazepine, phenytoin, phenobarbital, and primidone have been shown to increase the apparent clearance of lamotrigine. Estrogen-containing oral contraceptives and other drugs, such as rifampin and protease inhibitors lopinavir/ritonavir and atazanavir/ritonavir, that induce lamotrigine glucuronidation have also been shown to increase the apparent clearance of lamotrigine (see Drug Interactions (7)).

#### Absorption

Lamotrigine is rapidly and completely absorbed after oral administration with negligible first pass metabolism (absolute bioavailability is 98%). The bioavailability is not affected by food. Peak plasma concentrations occur anywhere from 1.4 to 4.8 hours following drug administration.

#### Dose Proportionality

In healthy volunteers not receiving any other medications and given single doses, the plasma concentrations of lamotrigine increased in direct proportion to the dose administered over the range of 50 to 400 mg. In 2 small studies (N = 7 and 8) of patients with epilepsy who were maintained on other AEDs, there also was a linear relationship between dose and lamotrigine plasma concentrations at steady state following doses of 50 to 350 mg twice daily.

#### Distribution

Estimates of the mean apparent volume of distribution (V<sub>d</sub>F) of lamotrigine following oral administration ranged from 0.9 to 1.3 L/kg. V<sub>d</sub>F is independent of dose and is similar following single and multiple doses in both patients with epilepsy and in healthy volunteers.

#### Protein Binding

Data from in vitro studies indicate that lamotrigine is approximately 55% bound to human plasma proteins at plasma lamotrigine concentrations from 1 to 10 mcg/mL (10 mcg/mL is 4 to 6 times the trough plasma concentration observed in the controlled efficacy trials). Because lamotrigine is not highly bound to plasma proteins, clinically significant interactions with other drugs through competition for protein binding sites are unlikely. The binding of lamotrigine to plasma proteins did not change in the presence of the therapeutic concentrations of phenytoin, phenobarbital, or valproate. Lamotrigine did not displace other AEDs (carbamazepine, phenytoin, phenobarbital) from protein-binding sites.

#### Metabolism

Lamotrigine is metabolized predominantly by glucuronic acid conjugation; the major metabolite is an inactive 2-N-glucuronide conjugate. After oral administration of 240 mg of <sup>14</sup>C-lamotrigine (15 µCi) to 6 healthy volunteers, 94% was recovered in the urine and 2% was recovered in the feces. The radioactivity in the urine consisted of unchanged lamotrigine (10%), the 2-N-glucuronide (76%), a 5-N-glucuronide (10%), a 2-N-methyl metabolite (0.14%), and other unidentified minor metabolites (4%).

#### Enzyme Induction

The effects of lamotrigine on the induction of specific families of mixed-function oxidase isozymes have not been systematically evaluated.

Following multiple administrations (150 mg twice daily) to normal volunteers taking no other medications, lamotrigine induced its own metabolism, resulting in a 25% decrease in t<sub>1/2</sub> and a 37% increase in CL/F at steady state compared with values obtained in the same volunteers following a single dose. Evidence gathered from other sources suggests that self-induction by lamotrigine may not occur when lamotrigine is given as adjunctive therapy in patients receiving enzyme-inducing drugs such as carbamazepine, phenytoin, phenobarbital, primidone, or other drugs such as rifampin and the protease inhibitors lopinavir/ritonavir and atazanavir/ritonavir that induce lamotrigine glucuronidation (see Drug Interactions (7)).

#### Elimination

The elimination half-life and apparent clearance of lamotrigine following oral administration of SUBVENTE to adult subjects with epilepsy and healthy volunteers is summarized in Table 14. Half-life and apparent oral clearance vary depending on concomitant AEDs.

#### Drug Interactions

The apparent clearance of lamotrigine is affected by the coadministration of certain medications (see Warnings and Precautions (5.6, 5.12), Drug Interactions (7)).

The net effects of drug interactions with lamotrigine are summarized in Tables 13 and 15, followed by details of the drug interaction studies below.

Table 15. Summary of Drug Interactions with Lamotrigine

Drug	Drug Plasma Concentration with Adjunctive Lamotrigine	Lamotrigine Plasma Concentration with Adjunctive Drugs
Oral contraceptives (e.g., ethinyl loestradiol/levonorgestrel) <sup>1</sup>	-- <sup>†</sup>	↓
Aripiprazole	Not assessed	-- <sup>†</sup>
Azaxone/ritonavir	-- <sup>†</sup>	↓
Bupropion	Not assessed	--
Carbamazepine	--	↓
Carbamazepine epoxide <sup>2</sup>	?	?
Felbamate	Not assessed	--
Gabapentin	Not assessed	--
lacosamide	Not assessed	--
Levetiracetam	--	--
Lithium	--	Not assessed

<sup>1</sup>From adjunctive clinical trials and volunteer trials.

<sup>2</sup>Net effects were estimated by comparing the mean clearance values obtained in adjunctive clinical trials and volunteer trials.

<sup>3</sup>The effect of other hormonal contraceptive preparations or hormone replacement therapy on the pharmacokinetics of lamotrigine has not been systematically evaluated in clinical trials, although the effects may be similar to that seen with the ethinylestradiol/levonorgestrel combination.

<sup>4</sup>Modest decrease in levetiracetam.

<sup>5</sup>Slight decrease, not expected to be clinically meaningful.

<sup>6</sup>Compared with historical controls.

<sup>7</sup>Not administered, but an active metabolite of carbamazepine.

<sup>8</sup>Not administered, but an active metabolite of oxcarbazepine.

<sup>9</sup>Not administered, but an active metabolite of primidone.

<sup>10</sup>Slight increase, not expected to be clinically meaningful.

-- = No significant effect.

† = Conflicting data.

#### Estrogen-Containing Oral Contraceptives

In 16 female volunteers, an oral contraceptive preparation containing 30 mcg ethinylestradiol and 150 mcg levonorgestrel increased the apparent clearance of lamotrigine (300 mg/day) by approximately 2-fold with mean decreases in AUC of 52% and in C<sub>max</sub> of 39%. In this study, trough serum lamotrigine concentrations gradually increased and were approximately 2-fold higher on average at the end of the week of the active hormone preparation compared with trough lamotrigine concentrations at the end of the active hormone cycle.

Gradual transient increases in lamotrigine plasma levels (approximately 2-fold increase) occurred during the week of inactive hormone preparation (pill-free weeks) for women not also taking a drug that increases the clearance of lamotrigine (carbamazepine, phenytoin, phenobarbital, primidone, or other drugs such as rifampin and the protease inhibitors lopinavir/ritonavir and atazanavir/ritonavir that reduce lamotrigine glucuronidation) (see Drug Interactions (7)). The increase in lamotrigine plasma levels will be greater if the dose of SUBVENTE is increased in the few days before or during the pill-free week. Increases in lamotrigine plasma levels could result in dose-dependent adverse reactions.

In the same study, coadministration of lamotrigine (300 mg/day) in 16 female volunteers did not affect the pharmacokinetics of the ethinylestradiol component of the oral contraceptive preparation. There were mean decreases in the AUC and C<sub>max</sub> of the levonorgestrel component of 19% and 12%, respectively. Measurement of serum progesterone indicated that there was no hormonal evidence of ovulation in any of the 16 volunteers, although measurement of serum FSH, LH, and estradiol indicated that there was some loss of suppression of the hypothalamic-pituitary-ovarian axis.

The effects of doses of lamotrigine other than 300 mg/day have not been systematically evaluated in controlled clinical trials. Studies with other female hormonal preparations (including progestin/progesterone-containing IUDs) have not been conducted.

The clinical significance of the observed hormonal changes on ovulatory activity is unknown. However, the possibility of decreased contraceptive efficacy in some patients cannot be excluded. Therefore, patients should be instructed to promptly report

changes in their menstrual pattern (e.g., break-through bleeding). Dosage adjustments may be necessary for women receiving estrogen-containing products, including oral contraceptive preparations (see Dosage and Administration (2.1)).

**Other Hormonal Contraceptives or Hormone Replacement Therapy**

The effect of other hormonal contraceptive preparations or hormone replacement therapy on the pharmacokinetics of lamotrigine has not been systematically evaluated. It has been reported that ethinyl estradiol, not progestogens, increased the clearance of lamotrigine to 2-fold, and the progestin-only pills had no effect on lamotrigine plasma levels. Therefore, adjustments to the dosage of SUBVENTO in the presence of progestogens alone will likely not be needed.

**Atazanavir**

In 18 patients with bipolar disorder on a stable regimen of 100 to 400 mg/day of lamotrigine, the lamotrigine AUC and C<sub>max</sub> were reduced by approximately 10% in patients who received atazanavir 10 to 30 mg/day for 7 days, followed by 100 mg/day for an additional 7 days. This reduction in lamotrigine exposure is not considered clinically meaningful.

**Atazanavir/Isoniazid**

In a study in healthy volunteers, daily doses of atazanavir/isoniazid (300 mg/100 mg) reduced the plasma AUC and C<sub>max</sub> of lamotrigine (single 100 mg dose) by an average of 32% and 6%, respectively, and shortened the elimination half-lives by 21%. In the presence of atazanavir/isoniazid (300 mg/100 mg), the metabolite to lamotrigine ratio was increased from 0.45 to 0.73 consistent with induction of glucuronidation. The pharmacokinetics of atazanavir/isoniazid were similar in the presence of concomitant lamotrigine to the historical data of the pharmacokinetics in the absence of lamotrigine.

**Bupropion**

The pharmacokinetics of a 100-mg single dose of lamotrigine in healthy volunteers (n = 12) were not changed by coadministration of bupropion sustained-release formulation (150 mg twice daily) starting 13 days before lamotrigine.

**Carbamazepine**

Lamotrigine has no appreciable effect on steady-state carbamazepine plasma concentration. Limited clinical data suggest there is a higher incidence of dizziness, diplopia, ataxia, and blurred vision in patients receiving carbamazepine with lamotrigine than in patients receiving either AEDs with lamotrigine (see Adverse Reactions (4.7)). The mechanism of this interaction is unclear. The effect of lamotrigine on plasma concentrations of carbamazepine-epoxide is unclear. In a small subset of patients (n = 7) studied in a placebo-controlled trial, lamotrigine had no effect on carbamazepine epoxide plasma concentrations, but in a small, uncontrolled study (n = 9), carbamazepine-epoxide levels increased.

The addition of carbamazepine decreases lamotrigine steady-state concentrations by approximately 40%.

**Felbamate**

In a trial in 21 healthy volunteers, coadministration of felbamate (1,200 mg twice daily) with lamotrigine (100 mg twice daily for 10 days) appeared to have no clinically relevant effects on the pharmacokinetics of lamotrigine.

**Folate Inhibitors**

Lamotrigine is a weak inhibitor of dihydrofolate reductase. Prescribers should be aware of this action when prescribing other medications that inhibit folate metabolism.

**Lacosamide**

Plasma concentrations of lamotrigine were not affected by concomitant lacosamide (200, 400, or 600 mg/day) in placebo-controlled clinical trials in patients with partial-onset seizures.

**Clonazepam**

Based on a retrospective analysis of plasma levels in 34 subjects who received lamotrigine both with and without gabapentin, gabapentin does not appear to change the apparent clearance of lamotrigine.

**Levetiracetam**

Potential drug interactions between levetiracetam and lamotrigine were assessed by evaluating serum concentrations of both agents during placebo-controlled clinical trials. These data indicate that lamotrigine does not influence the pharmacokinetics of levetiracetam and that levetiracetam does not influence the pharmacokinetics of lamotrigine.

**Lithium**

The pharmacokinetics of lithium were not altered in healthy subjects (n = 20) by coadministration of lamotrigine (100 mg/day) for 6 days.

**Lopinavir/Ritonavir**

The addition of lopinavir (400 mg twice daily)/ritonavir (100 mg twice daily) decreased the AUC, C<sub>max</sub>, and elimination half-life of lamotrigine by approximately 50% to 55.4% in 18 healthy subjects. The pharmacokinetics of lopinavir/ritonavir were similar with concomitant lamotrigine, compared with that in historical controls.

**Olanzapine**

The AUC and C<sub>max</sub> of olanzapine were similar following the addition of olanzapine (15 mg once daily) to lamotrigine (200 mg once daily) in healthy male volunteers (n = 16) compared with the AUC and C<sub>max</sub> of healthy male volunteers receiving olanzapine alone (n = 16).

In the same trial, the AUC and C<sub>max</sub> of lamotrigine were reduced on average by 24% and 20%, respectively, following the addition of olanzapine to lamotrigine in healthy male volunteers compared with those receiving lamotrigine alone. This reduction in lamotrigine plasma concentrations is not expected to be clinically meaningful.

**Oxcarbazepine**

The AUC and C<sub>max</sub> of oxcarbazepine and its active 10-monohydroxy oxcarbazepine metabolite were not significantly different following the addition of oxcarbazepine (600 mg twice daily) to lamotrigine (200 mg once daily) in healthy male volunteers (n = 13) compared with healthy male volunteers receiving oxcarbazepine alone (n = 13).

In the same trial, the AUC and C<sub>max</sub> of lamotrigine were similar following the addition of oxcarbazepine (600 mg twice daily) to lamotrigine in healthy male volunteers compared with those receiving lamotrigine alone. Limited clinical data suggest a higher incidence of headache, dizziness, nausea, and somnolence with coadministration of lamotrigine and oxcarbazepine compared with lamotrigine alone or oxcarbazepine alone.

**Paracetamol**

In a pooled analysis of data from 3 placebo-controlled clinical trials investigating adjunctive paracetamol in patients with partial onset and PGLTC seizures, the highest paracetamol dose evaluated (12 mg/day) increased lamotrigine clearance by <10%. An effect of this magnitude is not considered to be clinically relevant.

**Phenobarbital/Primidone**

The addition of phenobarbital or primidone decreases lamotrigine steady-state concentrations by approximately 40%.

**Phenytoin**

Lamotrigine has no appreciable effect on steady-state phenytoin plasma concentrations in patients with epilepsy. The addition of phenytoin decreases lamotrigine steady-state concentrations by approximately 40%.

**Pregabalin**

Steady-state trough plasma concentrations of lamotrigine were not affected by concomitant pregabalin (200 mg 3 times daily) administration. There are no pharmacokinetic interactions between lamotrigine and pregabalin.

**Rifampin**

In 10 male volunteers, rifampin (600 mg/day for 5 days) significantly increased the apparent clearance of a single 25-mg dose of lamotrigine by approximately 2-fold (AUC decreased by approximately 48%).

**Risperidone**

In a 14 healthy volunteers study, multiple oral doses of lamotrigine 400 mg daily had no clinically significant effect on the single-dose pharmacokinetics of risperidone 2 mg and its active metabolite 9-OH risperidone. Following the coadministration of risperidone 2 mg with lamotrigine, 12 of the 14 volunteers reported somnolence compared with 1 out of 20 when risperidone was given alone, and none when lamotrigine was administered alone.

**Topiramate**

Topiramate resulted in no change in plasma concentrations of lamotrigine. Administration of lamotrigine resulted in a 15% increase in topiramate concentrations.

**Valproate**

When lamotrigine was administered to healthy volunteers (n=18) receiving valproate, the trough steady-state valproate plasma concentrations decreased by an average of 25% over a 3-week period, and then stabilized. However, adding lamotrigine to the existing therapy did not cause a change in valproate plasma concentrations in either adult or pediatric patients in controlled clinical trials.

The addition of valproate increased lamotrigine steady-state concentrations in normal volunteers by slightly more than 2-fold. In 1 trial, maximal inhibition of lamotrigine clearance was reached at valproate doses between 250 and 500 mg/day and did not increase as the valproate dose was further increased.

**Zonisamide**

In a study in 18 patients with epilepsy, coadministration of zonisamide (200 to 400 mg/day) with lamotrigine (150 to 300 mg/day for 35 days) had no significant effect on the pharmacokinetics of lamotrigine.

**Known Inhibitors or Inducers of Glucuronidation**

Drugs other than those listed above have not been systematically evaluated in combination with lamotrigine. Since lamotrigine is metabolized predominantly by glucuronic acid conjugation, drugs that are known to induce or inhibit glucuronidation may affect the apparent clearance of lamotrigine and doses of lamotrigine may require adjustment based on clinical response.

**Other**

In vitro assessment of the inhibitory effect of lamotrigine at OCT2 demonstrate that lamotrigine, but not the N(2)-glucuronide metabolite, is an inhibitor of OCT2 at potentially clinically relevant concentrations, with IC<sub>50</sub> value of 33.8 μM (see Drug Interactions (7)). Results of in vitro experiments suggest that clearance of lamotrigine is unlikely to be reduced by concomitant administration of amitriptyline, citalopram, cefazolin, fluoxetine, haloperidol, lorazepam, olanzapine, sertraline, or trazodone.

Results of in vitro experiments suggest that lamotrigine does not reduce the clearance of drugs eliminated predominantly by CYP2D6.

**Specific Populations**

**Patients with Renal Impairment:** Twelve volunteers with chronic renal failure (mean creatinine clearance: 13 mL/min; range: 6 to 23) and another 6 individuals undergoing hemodialysis were each given a single 100-mg dose of lamotrigine. The mean plasma half-lives determined in the study were 42.9 hours (chronic renal failure), 13.0 hours (during hemodialysis), and 57.4 hours (between hemodialyses) compared with 26.2 hours in healthy volunteers. On average, approximately 20% (range: 5 to 35.1) of the amount of lamotrigine present in the body was eliminated by hemodialysis during 4-hour session (see Dosage and Administration (2.1)).

**Patients with Hepatic Impairment:** The pharmacokinetics of lamotrigine following a single 100-mg dose of lamotrigine were evaluated in 24 subjects with mild, moderate, and severe hepatic impairment (Child-Pugh classification system) and compared with 12 subjects without hepatic impairment. The subjects with severe hepatic impairment were without ascites (n = 2) or with ascites (n = 5). The mean apparent clearances of lamotrigine in subjects with mild (n = 12), moderate (n = 8), severe without ascites (n = 2), and severe with ascites (n = 5) liver impairment were 0.39 ± 0.09, 0.24 ± 0.1, 0.04, and 0.15 ± 0.09 mL/min/kg, respectively, as compared with 0.27 ± 0.1 mL/min/kg in the healthy controls. Mean half-lives of lamotrigine in subjects with mild, moderate, severe without ascites, and severe with ascites hepatic impairment were 46 ± 20, 17 ± 44, 67 ± 11, and 100 ± 48 hours, respectively, as compared with 33 ± 7 hours in healthy controls (see Dosage and Administration (2.1)).

**Pediatric Patients:** The pharmacokinetics of lamotrigine following a single 2 mg/kg dose were evaluated in 2 studies in pediatric subjects (n = 29 for subjects aged 10 months to 5.9 years and n = 26 for subjects aged 5 to 11 years). Forty-three subjects received concomitant therapy with other AEDs and 12 subjects received lamotrigine as monotherapy. Lamotrigine pharmacokinetic parameters for pediatric patients are summarized in Table 16.

Population pharmacokinetic analyses involving subjects aged 2 to 18 years demonstrated that lamotrigine clearance was influenced predominantly by total body weight and concurrent AED therapy. The oral clearance of lamotrigine was higher, on a body weight basis, in pediatric patients than in adults. Weight-normalized lamotrigine clearance was higher in those subjects weighing <30 kg compared with those weighing >30 kg. Accordingly, patients weighing <30 kg may need an increase of as much as 50% in maintenance doses, based on clinical response, as compared with subjects weighing >30 kg being administered the same AEDs (see Dosage and Administration (2.2)). These analyses also revealed that, after accounting for body weight, lamotrigine clearance was not significantly influenced by age. Thus, the same weight-adjusted doses should be administered to children irrespective of differences in age. Concomitant AEDs which influence lamotrigine clearance in adults were found to have similar effects in children.

**Table 16. Mean Pharmacokinetic Parameters in Pediatric Subjects with Epilepsy**

Pediatric Study Population	Number of Subjects	T <sub>max</sub> (h)	T <sub>1/2</sub> (h)	CL/F (mL/min/kg)
Agtes 10 months to 5.3 years				

Subjects taking carbamazepine, phenytoin, phenobarbital, or primidone <sup>a</sup>	10	3.0 (1.0 to 5.9)	7.7 (5.7 to 11.4)	1.62 (2.44 to 5.28)
Subjects taking antiepileptic drugs with no known effect on the apparent clearance of lamotrigine	7	5.2 (2.9 to 6.1)	19.0 (12.9 to 27.1)	1.2 (0.75 to 2.42)
Subjects taking valproate only	8	2.5 (1.0 to 6.0)	44.9 (29.3 to 52.3)	0.47 (0.23 to 0.77)
<b>Ages 5 to 11 years</b>				
Subjects taking carbamazepine, phenytoin, phenobarbital, or primidone <sup>a</sup>	7	6.1 (1.0 to 3.0)	7.0 (7.0 to 9.8)	2.54 (1.35 to 5.58)
Subjects taking carbamazepine, phenytoin, phenobarbital, or primidone <sup>a</sup> plus valproate	8	3.3 (1.0 to 6.4)	19.1 (7.0 to 31.2)	0.89 (0.39 to 1.93)
Subjects taking valproate only <sup>b</sup>	3	5.5 (3.0 to 6.0)	65.8 (50.7 to 73.7)	0.24 (0.21 to 0.26)
<b>Ages 13 to 18 years</b>				
Subjects taking carbamazepine, phenytoin, phenobarbital, or primidone <sup>a</sup>	11	— <sup>c</sup>	— <sup>c</sup>	1.3
Subjects taking carbamazepine, phenytoin, phenobarbital, or primidone <sup>a</sup> plus valproate	8	— <sup>c</sup>	— <sup>c</sup>	0.5
Subjects taking valproate only	4	— <sup>c</sup>	— <sup>c</sup>	0.3

<sup>a</sup>Carbamazepine, phenytoin, phenobarbital, and primidone have been shown to increase the apparent clearance of lamotrigine. Estrogen-containing oral contraceptives, rifampin, and the protease inhibitors lopinavir/ritonavir and atazanavir/ritonavir have also been shown to increase the apparent clearance of lamotrigine (see Drug Interactions).  
<sup>b</sup>Two subjects were included in the calculation for mean Tmax.  
<sup>c</sup>Parameter not estimated.

**Geriatric Patients:** The pharmacokinetics of lamotrigine following a single 150-mg dose of lamotrigine were evaluated in 12 elderly volunteers between the ages of 65 and 78 years (mean creatinine clearance = 61 mL/min; range: 33 to 103 mL/min). The mean half-life of lamotrigine in these subjects was 31.2 hours (range: 24.5 to 43.4 hours), and the mean clearance was 0.40 mL/min/kg (range: 0.26 to 0.48 mL/min/kg).

**Male and Female Patients:** The clearance of lamotrigine is not affected by gender. However, during dose escalation of lamotrigine in a clinical trial in patients with epilepsy on a stable dose of valproate (n = 7), mean trough lamotrigine concentrations unadjusted for weight were 24% to 45% higher (0.3 to 1.7 mcg/mL) in females than in males.

**Racial or Ethnic Groups:** The apparent oral clearance of lamotrigine was 25% lower in non-Caucasians than Caucasians.

### 13 NONCLINICAL TOXICOLOGY

#### 13.1 Carcinogenesis, Mutagenesis, Impairment of Fertility

No evidence of carcinogenicity was seen in mice or rats following oral administration of lamotrigine for up to 2 years at doses up to 30 mg/kg/day and 10 to 15 mg/kg/day, respectively. The highest doses tested are less than the human dose of 400 mg/day on a body surface area (mg/m<sup>2</sup>) basis.

Lamotrigine was negative in *in vitro* genotoxicity assays (Ames and mouse lymphoma tk) and in cytogenetic (i) *in vitro* human lymphocyte and *in vivo* rat bone marrow assays.

No evidence of impaired fertility was detected in rats given oral doses of lamotrigine up to 20 mg/kg/day. The highest dose tested is less than the human dose of 400 mg/day on a mg/m<sup>2</sup> basis.

### 14 CLINICAL STUDIES

#### 14.1 Epilepsy

##### Monotherapy with Lamotrigine in Adults with Partial-Onset Seizures Already Receiving Treatment with Carbamazepine, Phenytoin, Phenobarbital, or Primidone as the Single Antiepileptic Drug

The effectiveness of monotherapy with lamotrigine was established in a multicenter, double-blind clinical trial enrolling 156 adult outpatients with partial-onset seizures. The patients experienced at least 4 simple partial-onset, complex partial-onset, and/or secondarily generalized seizures during each of 2 consecutive 4-week periods while receiving carbamazepine or phenytoin monotherapy during baseline. Lamotrigine (target dose of 500 mg/day) or valproate (1,000 mg/day) was added to either carbamazepine or phenytoin monotherapy over a 4-week period. Patients were then converted to monotherapy with lamotrigine or valproate during the next 4 weeks, then continued on monotherapy for an additional 12-week period.

Trial endpoints were completion of all weeks of trial treatment or meeting an escape criterion. Criteria for escape relative to baseline were: (1) doubling of average monthly seizure count, (2) doubling of highest consecutive 2-day seizure frequency, (3) emergence of a new seizure type (defined as a seizure that did not occur during the 8-week baseline) that is more severe than seizure types that occur during study treatment, or (4) clinically significant prolongation of generalized tonic-clonic seizures. The primary efficacy variable was the proportion of patients in each treatment group who met escape criteria.

The percentages of patients who met escape criteria were 42% (32/76) in the group receiving lamotrigine and 60% (35/58) in the valproate group. The difference in the percentage of patients meeting escape criteria was statistically significant (P = 0.0012) in favor of lamotrigine. No differences in efficacy based on age, sex, or race were detected.

Patients in the control group were intentionally treated with a relatively low dose of valproate, as such, the sole objective of the trial was to demonstrate the effectiveness and safety of monotherapy with lamotrigine, and cannot be interpreted to imply the superiority of lamotrigine to an adequate dose of valproate.

##### Adjuvantive Therapy with Lamotrigine in Adults with Partial-Onset Seizures

The effectiveness of lamotrigine as adjuvantive therapy (added to other AEDs) was initially established in 3 pivotal, multicenter, placebo-controlled, double-blind clinical trials in 355 adults with refractory partial-onset seizures. The patients had a history of at least 4 partial-onset seizures per month in spite of receiving 1 or more AEDs at therapeutic concentrations and in 2 of the trials were observed on other established AED regimens during baselines that varied between 8 to 12 weeks. In the third trial, patients were not observed in a prospective baseline. In patients continuing to have at least 4 seizures per month during the baseline, lamotrigine or placebo was then added to the existing therapy. In all 3 trials, change from baseline in seizure frequency was the primary measure of effectiveness. The results given below are for all partial-onset seizures in the intent-to-treat population (all patients who received at least 1 dose of treatment) in each trial, unless otherwise indicated. The median seizure frequency at baseline was 3 per week while the mean at baseline was 6.6 per week for all patients enrolled in efficacy trials.

One trial (n = 216) was a double-blind, placebo-controlled, parallel trial consisting of a 24-week treatment period. Patients could not be on more than 2 other anticonvulsants and valproate was not allowed. Patients were randomized to receive placebo, a target dose of 300 mg/day of lamotrigine, or a target dose of 500 mg/day of lamotrigine. The median reductions in the frequency of all partial-onset seizures relative to baseline were 8% in patients receiving placebo, 20% in patients receiving 300 mg/day of lamotrigine, and 36% in patients receiving 500 mg/day of lamotrigine. The seizure frequency reduction was statistically significant in the 500-mg/day group compared with the placebo group, but not in the 300-mg/day group.

A second trial (n = 98) was a double-blind, placebo-controlled, randomized, crossover trial consisting of two 14-week treatment periods (the last 2 weeks of which consisted of dose tapering) separated by a 4-week washout period. Patients could not be on more than 2 other anticonvulsants and valproate was not allowed. The target dose of lamotrigine was 400 mg/day. When the first 12 weeks of the treatment periods were analyzed, the median change in seizure frequency was a 25% reduction on lamotrigine compared with placebo (P < 0.001).

The third trial (n = 41) was a double-blind, placebo-controlled, crossover trial consisting of two 12-week treatment periods separated by a 4-week washout period. Patients could not be on more than 2 other anticonvulsants. Thirteen patients were on concomitant valproate; these patients received 150 mg/day of lamotrigine. The 28 other patients had a target dose of 300 mg/day of lamotrigine. The median change in seizure frequency was a 26% reduction on lamotrigine compared with placebo (P < 0.01). No differences in efficacy based on age, sex, or race, as measured by change in seizure frequency, were detected.

##### Adjuvantive Therapy with Lamotrigine in Pediatric Patients with Partial-Onset Seizures

The effectiveness of lamotrigine as adjuvantive therapy in pediatric patients with partial-onset seizures was established in a multicenter, double-blind, placebo-controlled trial in 199 patients aged 2 to 16 years (n = 98 on lamotrigine, n = 101 on placebo). Following an 8-week baseline phase, patients were randomized to 18 weeks of treatment with lamotrigine or placebo added to their current AED regimen of up to 2 drugs. Patients were dosed based on body weight and valproate use. Target doses were designed to approximate 5 mg/kg/day for patients taking valproate (maximum dose: 250 mg/day) and 15 mg/kg/day for the patients not taking valproate (maximum dose: 750 mg/day). The primary efficacy endpoint was percentage change from baseline in all partial-onset seizures. For the intent-to-treat population, the median reduction of all partial-onset seizures was 36% in patients treated with lamotrigine and 7% on placebo, a difference that was statistically significant (P < 0.01).

##### Adjuvantive Therapy with Lamotrigine in Pediatric and Adult Patients with Lennox-Gastaut Syndrome

The effectiveness of lamotrigine as adjuvantive therapy in patients with Lennox-Gastaut syndrome was established in a multicenter, double-blind, placebo-controlled trial in 169 patients aged 3 to 25 years (n = 74 on lamotrigine, n = 95 on placebo). Following a 4-week, single-blind, placebo phase, patients were randomized to 16 weeks of treatment with lamotrigine or placebo added to their current AED regimen of up to 3 drugs. Patients were dosed on a fixed-dose regimen based on body weight and valproate use. Target doses were designed to approximate 5 mg/kg/day for patients taking valproate (maximum dose: 200 mg/day) and 15 mg/kg/day for patients not taking valproate (maximum dose: 400 mg/day). The primary efficacy endpoint was percentage change from baseline in major motor seizures (atonic, tonic, major myoclonic, and tonic-clonic seizures). For the intent-to-treat population, the median reduction of major motor seizures was 32% in patients treated with lamotrigine and 9% on placebo, a difference that was statistically significant (P < 0.05). Drop attacks were significantly reduced by lamotrigine (34%) compared with placebo (9%), as were tonic-clonic seizures (36% reduction versus 10% increase for lamotrigine and placebo, respectively).

##### Adjuvantive Therapy with Lamotrigine in Pediatric and Adult Patients with Primary Generalized Tonic-Clonic Seizures

The effectiveness of lamotrigine as adjuvantive therapy in patients with PGTIC seizures was established in a multicenter, double-blind, placebo-controlled trial in 113 pediatric and adult patients aged 2 years and older (n = 58 on lamotrigine, n = 59 on placebo). Patients with at least 3 PGTIC seizures during an 8-week baseline phase were randomized to 19 to 24 weeks of treatment with lamotrigine or placebo added to their current AED regimen of up to 2 drugs. Patients were dosed on a fixed-dose regimen, with target doses ranging from 3 to 12 mg/kg/day for pediatric patients and from 300 to 600 mg/day for adult patients based on concomitant AEDs.

The primary efficacy endpoint was percentage change from baseline in PGTIC seizures. For the intent-to-treat population, the median percent reduction in PGTIC seizures was 66% in patients treated with lamotrigine and 34% on placebo, a difference that was statistically significant (P = 0.006).

#### 14.2 Bipolar Disorder

##### Adults

The effectiveness of lamotrigine in the maintenance treatment of bipolar I disorder was established in 2 multicenter, double-blind, placebo-controlled trials in adult patients (aged 18 to 82 years) who met DSM-IV criteria for bipolar I disorder. Trial 1 enrolled patients with a current or recent (within 60 days) depressive episode as defined by DSM-IV and Trial 2 included patients with a current or recent (within 60 days) episode of mania or hypomania as defined by DSM-IV. Both trials included a cohort of patients (50% of 404 subjects in Trial 1 and 28% of 173 patients in Trial 2) with rapid cycling bipolar disorder (4 to 6 episodes per year).

In both trials, patients were treated to a target dose of 200 mg of lamotrigine as add-on therapy or as monotherapy with gradual withdrawal of any psychotropic medications during an 8- to 16-week open-label period. Overall 81% of 1,305 patients participating in the open-label period were receiving 1 or more other psychotropic medications, including benzodiazepines, selective serotonin reuptake inhibitors (SSRIs), atypical antipsychotics (including olanzapine, valproate, or lithium, during treatment of lamotrigine. Patients with a CGI-severity score of 3 or less maintained for at least 4 continuous weeks, including at least the first 4 weeks on monotherapy with lamotrigine, were randomized to a placebo-controlled double-blind treatment period for up to 18 months. The primary endpoint was TIME to intervention for a mood episode or one that was emerging, time to discontinuation for either an adverse event that was judged to be related to bipolar disorder, or for lack of efficacy. The mood episode could be depression, mania, hypomania, or a mixed episode.

In Trial 1, patients received double-blind monotherapy with lamotrigine 50 mg/day (n = 50), lamotrigine 200 mg/day (n = 124), lamotrigine 400 mg/day (n = 47), or placebo (n = 121). Lamotrigine (200- and 400-mg/day treatment groups combined) was superior to placebo in delaying the time to occurrence of a mood episode (Figure 1). Separate analyses of the 200- and 400-mg/day dose groups revealed no added benefit from the higher dose.

In Trial 2, patients received double-blind monotherapy with lamotrigine (100 to 400 mg/day, n = 59), or placebo (n = 70). Lamotrigine was superior to placebo in delaying time to occurrence of a mood episode (Figure 2). The mean dose of lamotrigine was about 211 mg/day.

Although these trials were not designed to separately evaluate time to the occurrence of depression or mania, a combined analysis for the 2 trials revealed a statistically significant benefit for lamotrigine over placebo in delaying the time to occurrence of both depression and mania, although the findings were more robust for depression.

**Figure 1 Kaplan-Meier Estimation of Cumulative Proportion of Patients with**

- a skin rash
- blistering or peeling of your skin
- hives
- painful sores in your mouth or around your eyes

These symptoms may be the first signs of a serious skin reaction. A healthcare provider should examine you to decide if you should continue taking SUBVENITE.

**2. Other serious reactions, including serious blood problems or liver problems.**

SUBVENITE can also cause other types of allergic reactions or serious problems that may affect organs and other parts of your body like your liver or blood cells. You may or may not have a rash with these types of reactions. Call your healthcare provider right away if you have any of these symptoms:

- fever
- frequent infections
- severe muscle pain
- swelling of your face, eyes, lips, or tongue
- swollen lymph glands
- unusual bruising or bleeding, looking pale
- weakness, fatigue
- yellowing of your skin or the white part of your eyes
- trouble walking or seeing
- seizures for the first time or happening more often
- pain and/or tenderness in the area towards the top of your stomach (enlarged liver and/or spleen)

3. In patients with known heart problems, the use of SUBVENITE may lead to a fast heart beat. Call your healthcare provider right away if you:

- have a fast, slow, or pounding heart beat.
- feel your heart skip a beat.
- have shortness of breath.
- have chest pain
- feel lightheaded.

**4. Like other antiepileptic drugs, SUBVENITE may cause suicidal thoughts or actions in a very small number of people, about 1 in 500.**

Call a healthcare provider right away if you have any of these symptoms, especially if they are new, worse, or worry you:

- thoughts about suicide or dying
- attempts to commit suicide
- new or worse depression
- new or worse anxiety
- feeling agitated or restless
- panic attacks
- trouble sleeping (insomnia)
- new or worse irritability
- acting aggressive, being angry, or violent
- acting on dangerous impulses
- an extreme increase in activity and talking (mania)
- other unusual changes in behavior or mood

**Do not stop SUBVENITE without first talking to a healthcare provider.**

- Stopping SUBVENITE suddenly can cause serious problems.
- Suicidal thoughts or actions can be caused by things other than medicines. If you have suicidal thoughts or actions, your healthcare provider may check for other causes.

**How can I watch for early symptoms of suicidal thoughts and actions in myself or a family member?**

- Pay attention to any changes, especially sudden changes, in mood, behaviors, thoughts, or feelings.
- Keep all follow-up visits with your healthcare provider as scheduled.
- Call your healthcare provider between visits as needed, especially if you are worried about symptoms.

**5. SUBVENITE may cause aseptic meningitis, a serious inflammation of the protective membrane that covers the brain and spinal cord.**

Call your healthcare provider right away if you have any of the following symptoms:

- headache
- fever
- nausea
- vomiting
- stiff neck
- rash
- unusual sensitivity to light
- muscle pains
- chills
- confusion
- drowsiness

Meningitis has many causes other than SUBVENITE, which your doctor would check for you developed meningitis while taking SUBVENITE.

**SUBVENITE can cause other serious side effects.** For more information ask your healthcare provider or pharmacist. Tell your healthcare provider if you have any side effect that bothers you. Be sure to read the section below entitled "What are the possible side effects of SUBVENITE?"

**6. People prescribed SUBVENITE have sometimes been given the wrong medicine because many medicines have names similar to SUBVENITE, so always check that you receive SUBVENITE.**

Taking the wrong medication can cause serious health problems. When your healthcare provider gives you a prescription for SUBVENITE:

- Make sure you can read it clearly.
- Talk to your pharmacist to check that you are given the correct medicine.
- Each time you fill your prescription, check the tablets you receive against the pictures of the tablets below.

These pictures show the distinct wording, colors, and shapes of the tablets that help to identify the right strength of SUBVENITE tablets. Immediately call your pharmacist if you receive a SUBVENITE tablet that does not look like one of the tablets shown below, as you may have received the wrong medication.

**SUBVENITE (lamotrigine) tablets**

Tablet Strength	SUBVENITE Dimensional Drawing
25 mg	
100 mg	
150 mg	
200 mg	

**What is SUBVENITE?**

- SUBVENITE is a prescription medicine used:
  - o together with other medicines to treat certain types of seizures (partial-onset seizures, primary generalized tonic-clonic seizures, generalized seizures of Lennox-Gastaut syndrome) in people aged 2 years and older.
  - o alone when changing from 1 other medicine used to treat partial-onset seizures in people aged 14 years and older.
  - o for the long-term treatment of bipolar I disorder to lengthen the time between mood episodes in people who have been treated for mood episodes with other medicine.
- It is not known if SUBVENITE is safe or effective in people younger than 18 years with mood episodes such as bipolar disorder or depression.
- It is not known if SUBVENITE is safe or effective when used alone as the first treatment of seizures.
- It is not known if SUBVENITE is safe or effective for people with mood episodes who have not already been treated with other medicines.
- SUBVENITE should not be used for acute treatment of manic or mixed mood episodes.

**Do not take SUBVENITE:**

- if you have had an allergic reaction to lamotrigine or to any of the inactive ingredients in SUBVENITE. See the end of this leaflet for a complete list of ingredients in SUBVENITE.

**Before taking SUBVENITE, tell your healthcare provider about all of your health conditions, including if you:**

- have had a rash or allergic reaction to another antiepileptic medicine.
- are of Asian origin, have had HLA-B\*57:01 testing before, and know you are carrying the genetic variant HLA-B\*57:01.
- have or have had depression, mood problems, or suicidal thoughts or behavior.
- have a history of heart problems or irregular heart beats or any of your family members have any heart problem, including genetic abnormalities.
- have had aseptic meningitis after taking SUBVENITE.
- are taking estrogen-containing products, including oral contraceptives (birth control pills) or other female hormonal medicines (such as hormone replacement therapy). Do not start or stop taking birth control pills or other female hormonal medicine until you have talked with your healthcare provider. Tell your healthcare provider if you have any changes in your menstrual pattern such as breakthrough bleeding. Stopping these medicines while you are taking SUBVENITE may cause side effects, such as dizziness, lack of coordination, or double vision. Starting these medicines may lessen how well SUBVENITE works.
- are pregnant or plan to become pregnant. It is not known if SUBVENITE may harm your unborn baby. If you become pregnant while taking SUBVENITE, talk to your healthcare provider about registering with the North American Antiepileptic Drug Pregnancy Registry. You can enroll in this registry by calling 1-888-233-2334. The purpose of this registry is to collect information about the safety of antiepileptic drugs during pregnancy.
- are breastfeeding. Lamotrigine passes into breast milk and may cause side effects in a breastfed baby. If you breastfeed while taking SUBVENITE, watch your baby closely for trouble breathing, episodes of temporarily stopping breathing, sleepiness, or poor sucking. Call your baby's healthcare provider right away if you see any of these problems. Talk to your healthcare provider about the best way to feed your baby if you take SUBVENITE.

**Tell your healthcare provider about all the medicines you take, including prescription and over-the-counter medicines, vitamins, and herbal supplements.**

SUBVENITE and certain other medicines may interact with each other. This may cause serious side effects. Show the medicines you take. Keep a list of them to show your healthcare provider and pharmacist when you get a medicine.

**How should I take SUBVENITE?**

- Take SUBVENITE exactly as prescribed.
- Your healthcare provider may change your dose. Do not change your dose without talking to your healthcare provider.
- Do not stop taking SUBVENITE without talking to your healthcare provider. Stopping SUBVENITE suddenly may cause serious problems. For example, if you have epilepsy and you stop taking SUBVENITE suddenly, you may have seizures that do not stop. Talk with your healthcare provider about how to stop SUBVENITE slowly.
- If you miss a dose of SUBVENITE, take it as soon as you remember. If it is almost time for your next dose, just skip the missed dose. Take the next dose at your regular time. **Do not take 2 doses at the same time.**
- If you take too much SUBVENITE, call your healthcare provider or your local Poison Control Center or go to the nearest hospital emergency room right away.
- You may not feel the full effect of SUBVENITE for several weeks.
- If you have epilepsy, tell your healthcare provider if your seizures get worse or if you have any new types of seizures.
- Swallow SUBVENITE whole.
- If you have trouble swallowing SUBVENITE tablets, tell your healthcare provider because there may be another form of SUBVENITE you can take.
- If you receive SUBVENITE in a blister pack, examine the blister pack before use. Do not use if blisters are torn, broken, or missing.

**What should I avoid while taking SUBVENITE?**

Do not drive, operate machinery, or do other dangerous activities until you know how SUBVENITE affects you.

**What are the possible side effects of SUBVENITE?**

SUBVENITE can cause serious side effects.

See "What is the most important information I should know about SUBVENITE?"

**Common side effects of SUBVENITE include:**

- dizziness
- tremor
- headache
- rash
- blurred or double vision
- fever
- lack of coordination
- abdominal pain
- infections, including seasonal flu
- sleepiness

- back pain
- nausea, vomiting
- diarrhea
- tiredness
- insomnia
- dry mouth
- stuffy nose
- sore throat

These are not all the possible side effects of SUBVENITE. Call your doctor for medical advice about side effects. You may report side effects to FDA at 1-800-FDA-1088.

**How should I store SUBVENITE?**

- Store SUBVENITE at 20° to 25°C (68° to 77°F); excursions permitted to 15° to 30°C (59° to 86°F) (See USP Controlled Room Temperature).

**Keep SUBVENITE and all medicines out of the reach of children.**

**General information about the safe and effective use of SUBVENITE.** Medicines are sometimes prescribed for purposes other than those listed in a Medication Guide. Do not use SUBVENITE for a condition for which it was not prescribed. Do not give SUBVENITE to other people, even if they have the same symptoms that you have. It may harm them. You may have a false positive result on a urine drug screening test. SUBVENITE may make the test result positive for another drug. If you require a urine drug screening test, tell the healthcare professional administering the test that you are taking SUBVENITE. You can ask your healthcare provider or pharmacist for information about SUBVENITE that is written for health professionals.

**What are the ingredients in SUBVENITE?**

Active ingredient: lamotrigine, USP.  
 Inactive ingredients: lactose monohydrate; magnesium stearate; microcrystalline cellulose; povidone; and sodium starch glycolate.
